

# STATUS OF THE ART OF THE NEW GENERATION OF MPGD DETECTORS

CESARE BINI  
SAPIENZA UNIVERSITÀ AND INFN ROMA

1

# PREMISE

- **A wide variety of Micro Pattern Gas Detectors (MPGD)** is today on the market, many developments are in progress, thanks to the improvements of the **photolithographic technologies**.
- **RD-51** is the “forum” for this kind of developments
- **COMPASS** has been and is a pioneer under several aspects.
- In this talk → prospects for the **LHC experiments upgrades**
  - Quest for large dimensions ( $\approx \text{m}^2$ ) detectors
  - Time resolutions at the “ns” level
  - Space resolutions at the “100  $\mu\text{m}$ ” level
  - Rate capability up to 10 kHz/cm<sup>2</sup> → MHz/cm<sup>2</sup>.

# OUTLINE

- Introduction
  - The MPGD and the LHC experiments
  - The upgrades of the LHC experiments
- GEM
  - The CMS muon spectrometer upgrade
  - The new detector for the ALICE large TPC
  - Possible new developments in LHCb
- MicroMegas
  - The New Small Wheel upgrade of the ATLAS muon spectrometer
  - The Large Eta Tagger upgrade
- Recent developments
  - Fast Time MicroPattern (FTM) concept
  - $\mu$ RWell concept
- Summary

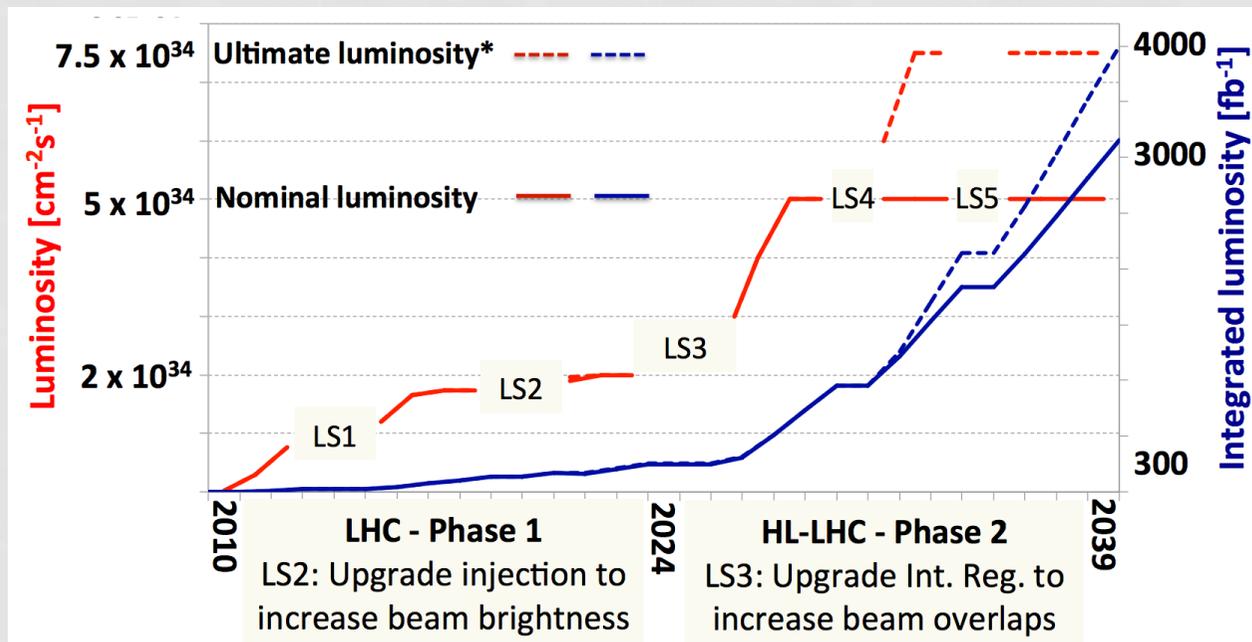

# INTRODUCTION - I

- First MPGD in the '90s: precision det. for high-rate applications
- At that time not mature enough to provide large area detectors for LHC experiments, with 2 “small” exceptions:
  - **LHCb M1** (20x20 cm<sup>2</sup> triple-GEMs for large- $\eta$  muon trigger)
  - **TOTEM T2** (half-circles triple-GEMs 14 cm radius)

# INTRODUCTION - II

- **LHC upgrades:** luminosity beyond baseline value → higher rates are expected in the forward muon detectors.
  - From p-p collisions:  $O(100 \text{ kHz/cm}^2)$  expected in the hottest regions
  - Heavy-ions collisions: bunch X-ing frequency up to 50 kHz (1 evt/20  $\mu\text{s}$ )
- **MPGD** now considered BUT → extension to large dimensions

# INTRODUCTION - III

- Upgrade projects involving MPGDs
- **ALICE** TPC Read-Out chambers
  - Quadruple- GEMs: 72 chambers  $0.2 \div 0.6 \text{ m}^2$  each (phase-I)
- **ATLAS** forward muon spectrometer
  - NEW SMALL WHELL: MicroMegas: 128 Q-plets  $2 \div 3 \text{ m}^2$  area each (phase-I)
  - LARGE ETA TAGGER: Pad MicroMegas Concept OR  $\mu$ PIC OR  $\mu$ RWELL
- **CMS** forward muon spectrometer
  - GE1/1: 72 Triple-GEMs chambers  $0.35 \div 0.4 \text{ m}^2$  each (phase-I)
  - ME0 + GE2/1: options considered (phase-II)
    - Triple-GEM with X-Y read-out
    - Fast Time MicroPattern new concept MPGD
    - $\mu$ RWELL new concept MPGD
- **LHCb** forward muon spectrometer
  - Still under discussion, probably small MPGDs ( $30 \times 30 \text{ cm}^2$ ) for triggering in a huge rate environment OR  $\mu$ RWELL

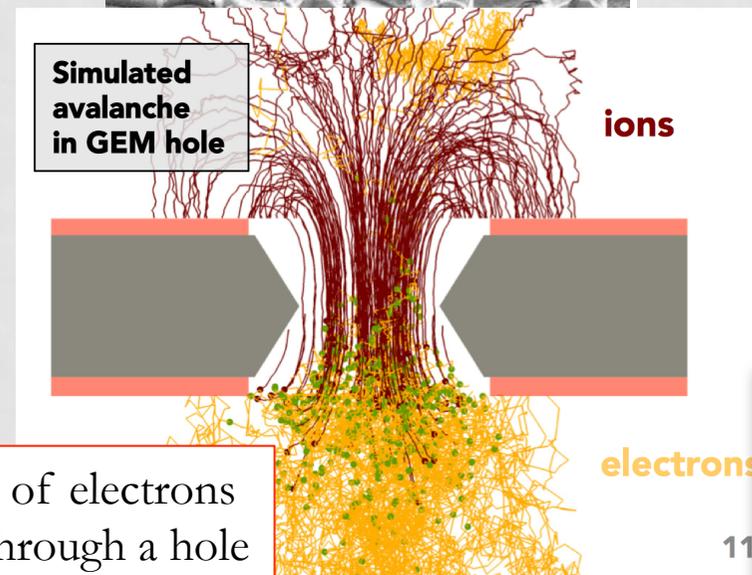

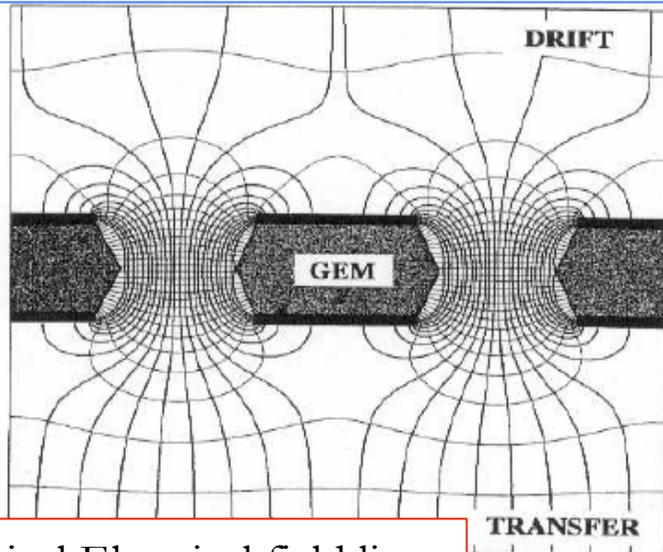

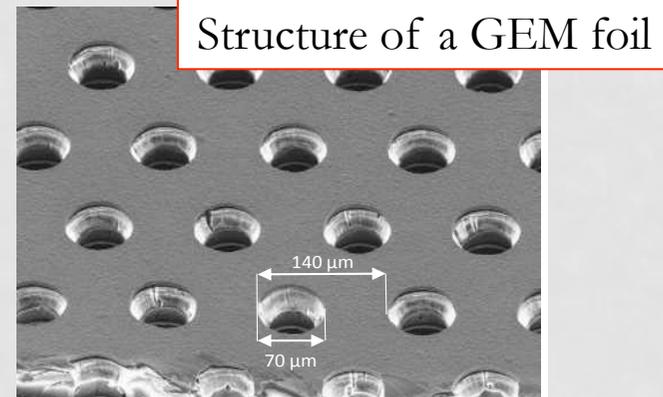

# GAS ELECTRON MULTIPLIERS: GEM

# MULTIPLE-GEM: PRINCIPLE OF OPERATION - I

**GEM foil:** high-quality polymer foil coated on both sides with thin metal layers; → shaped holes with a large electrical field inside

- Amplification avalanche in the hole region
- Mostly “transparent” for electrons
- Very small percentage of ions backflow
  - reduced space charge effect
  - reduced field distortion

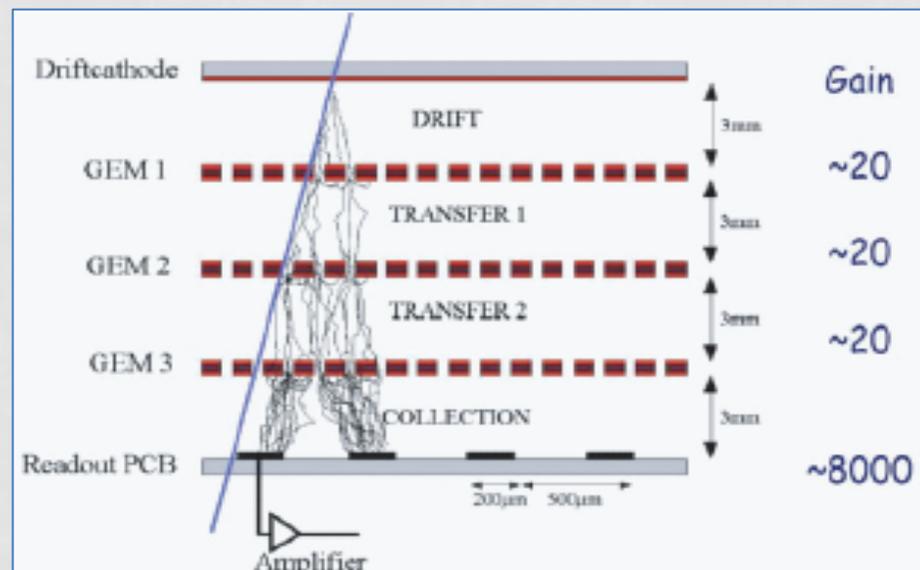

*F. Sauli, Nucl. Instr. and Meth. A386(1997)531*

Behaviour of electrons and ions through a hole

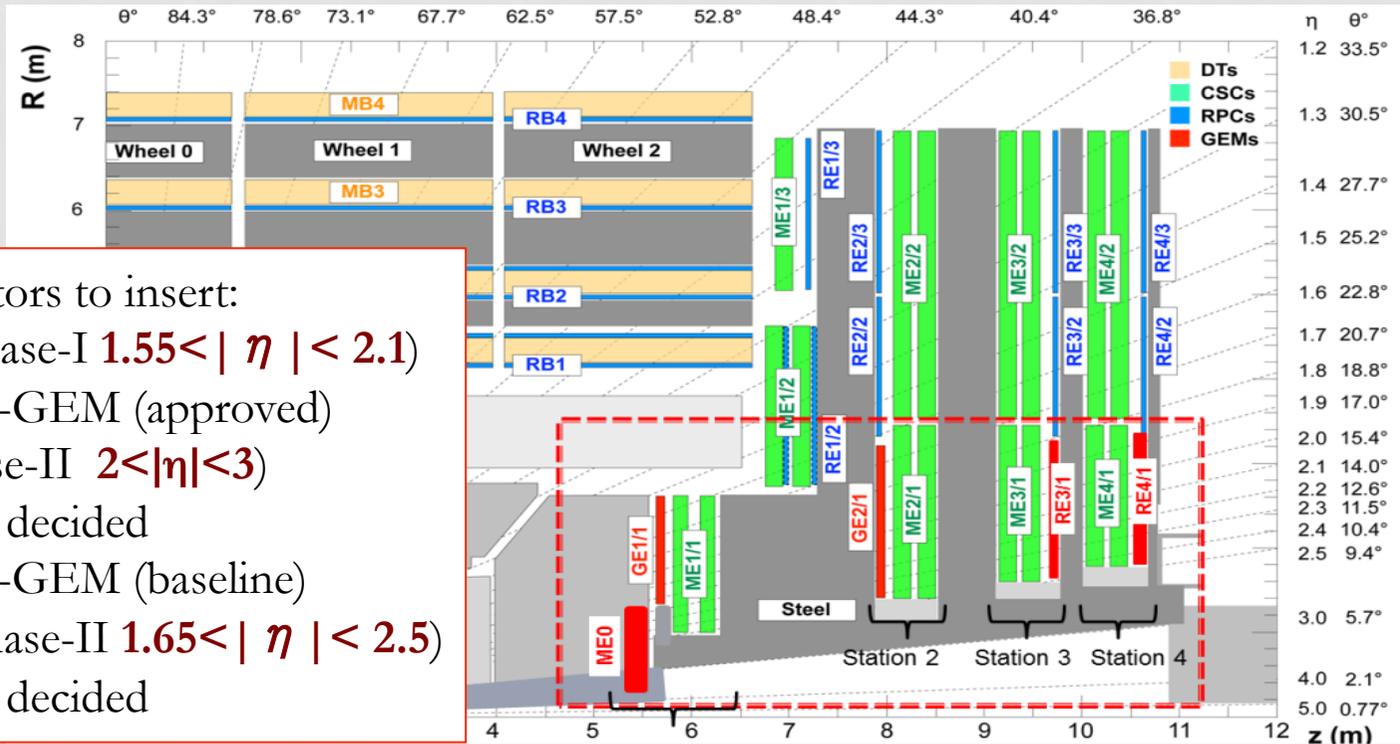

## MULTIPLE-GEM: PRINCIPLE OF OPERATION - II

- The technique has been extended to  $\approx \text{m}^2$  foils thanks to the *single-mask technology*  $\rightarrow$  **large area** applications are possible
- Then go to **Multiple-GEM** allowing:
  - High gain obtained with electrodes at “low voltages”  $\rightarrow$  less prone to discharges (*Raether limit hard to be reached*)
  - Freedom in the choice of the electrical fields  $\rightarrow$  optimization of the IBF (*Ion Back Flow*)  $\rightarrow$  reduction of field distortions

Status of the art of the new generation of  
MPGD detectors

# CMS: FORWARD MUON UPGRADE

New detectors to insert:

**GE1/1** (phase-I  $1.55 < |\eta| < 2.1$ )

Triple-GEM (approved)

**ME0** (phase-II  $2 < |\eta| < 3$ )

To be decided

Triple-GEM (baseline)

**GE2/1** (phase-II  $1.65 < |\eta| < 2.5$ )

To be decided

Requirements:

- Maximum geometric acceptance within the given CMS envelope
- **Rate capability** up to 100's kHz/cm<sup>2</sup>; no gain loss due to aging after 3000 fb<sup>-1</sup>
- Single-chamber **efficiency** > 98 % for mips; **gain uniformity** of < 10%
- High **angular** (<300 μrad) and good **time resolution** (<10 ns)

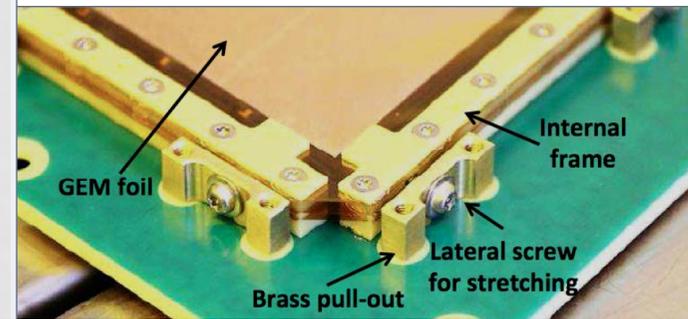

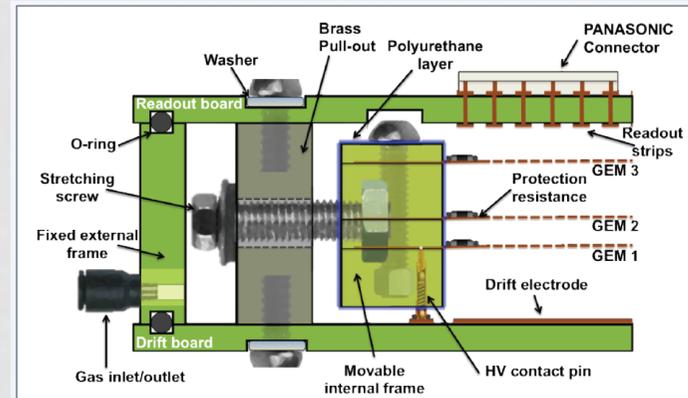

See CMS-TDR-013 CERN-LHCC-2015-012

# CMS GE1/1: LARGE SIZE TRIPLE-GEM

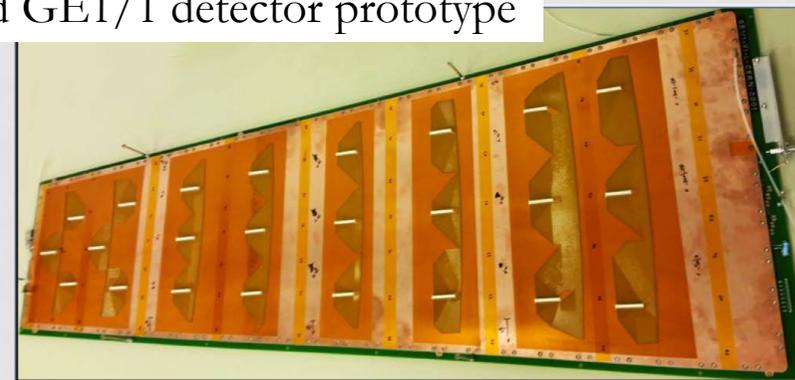

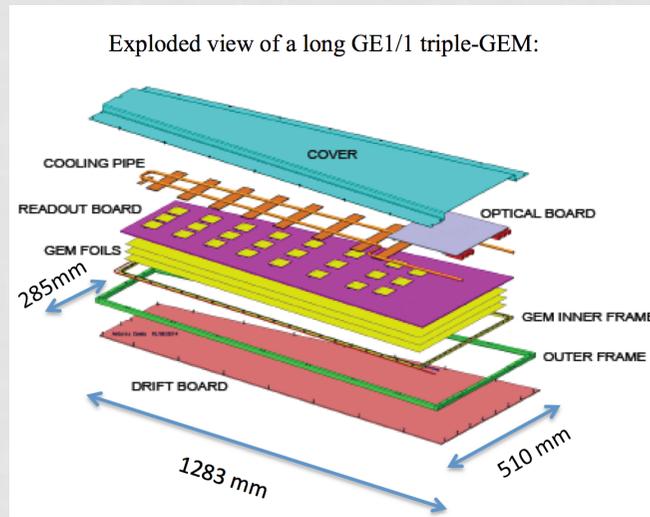

Major features of the GE1/1, design are:

- Single-mask technology exploited
- The three GEM foils: gap config (3/1/2/1)
- Readout board with strips (3072 per chamber) with fixed  $\phi$  pitch (463  $\mu$ rad)
- Internal frame with lateral stretching screws
- External frame

72 trapezoidal triple-GEM Superchambers  
 0.22 ÷ 0.45 m<sup>2</sup> size 1.28 m maximum length  
 Read-out through VFAT3

Assembled GE1/1 detector prototype

# CMS GE1/1: IMPACT ON TRIGGER

In CMS, the  $\phi$  coordinate is the precision one

- Radial strips with a fixed pitch in  $\phi$
- Tracks perpendicular → charge centroid

Muon trigger:  $\Delta\phi$  measured @ L1 trigger level

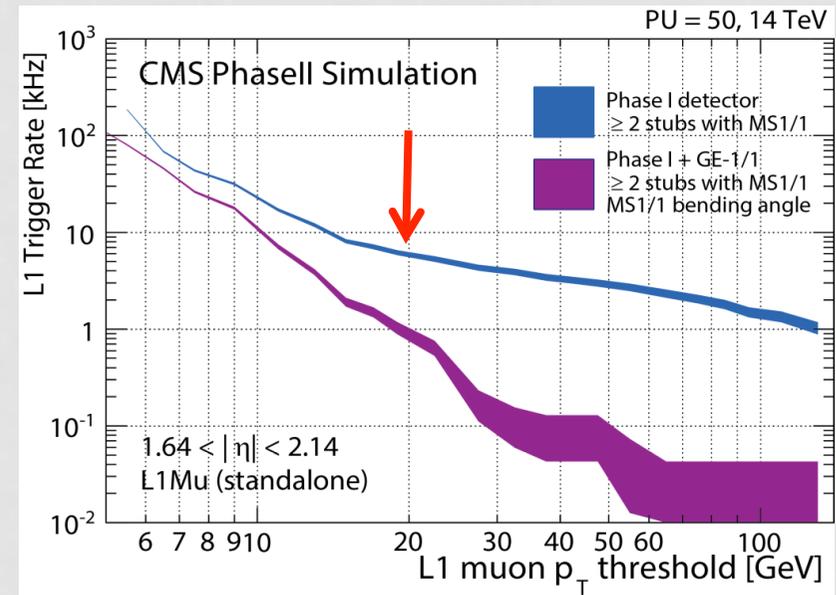

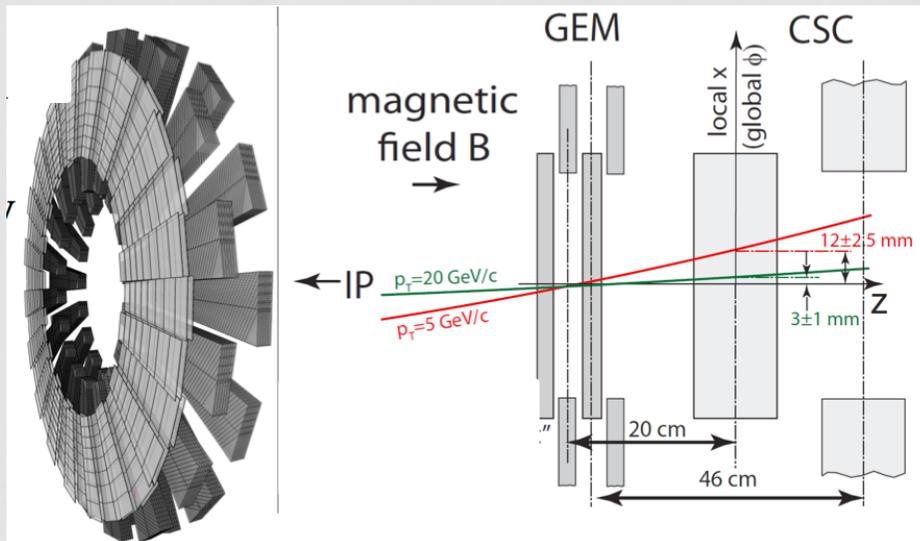

CSC+GEM improves the lever arm

- reduce fake muon rate

L1 single muon trigger rate reduction according to present simulation:

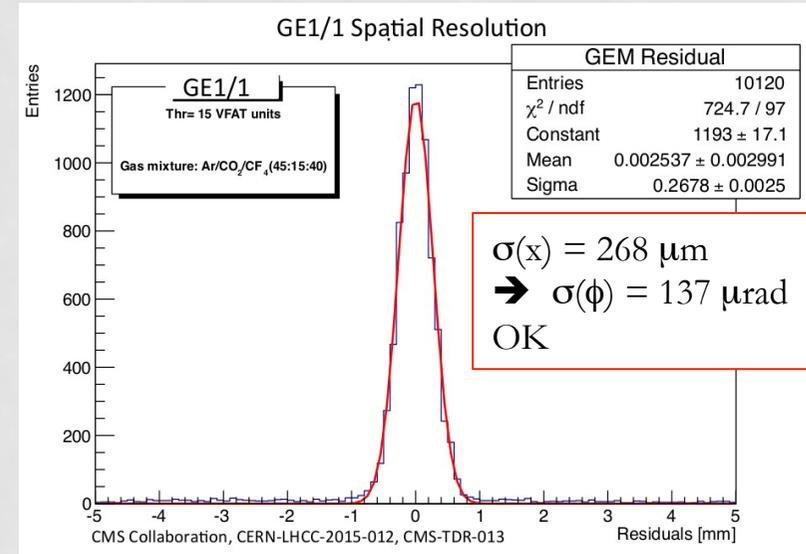

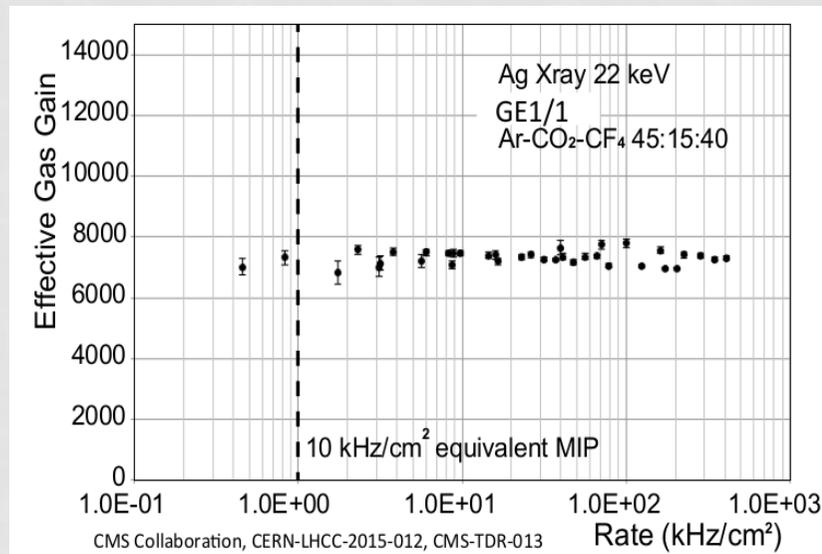

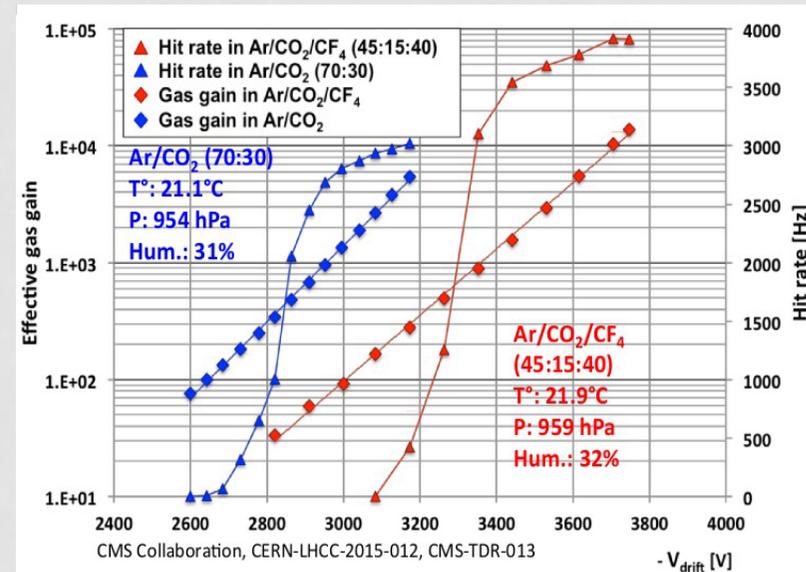

$p_T > 20$  GeV single muon trigger

Can be still used without prescale.

# CMS: PERFORMANCE OF LARGE PROTOTYPES

- Test-beam results on prototypes with two different gas mixtures
- At gains  $\approx 10^4$  efficiency plateau and high rate operations
- Time resolution  $\approx 7$  ns
- Triple-GEM technology perfectly meets the requirements imposed by the HL-LHC

# CMS: TRIPLE-GEM FOR ME0

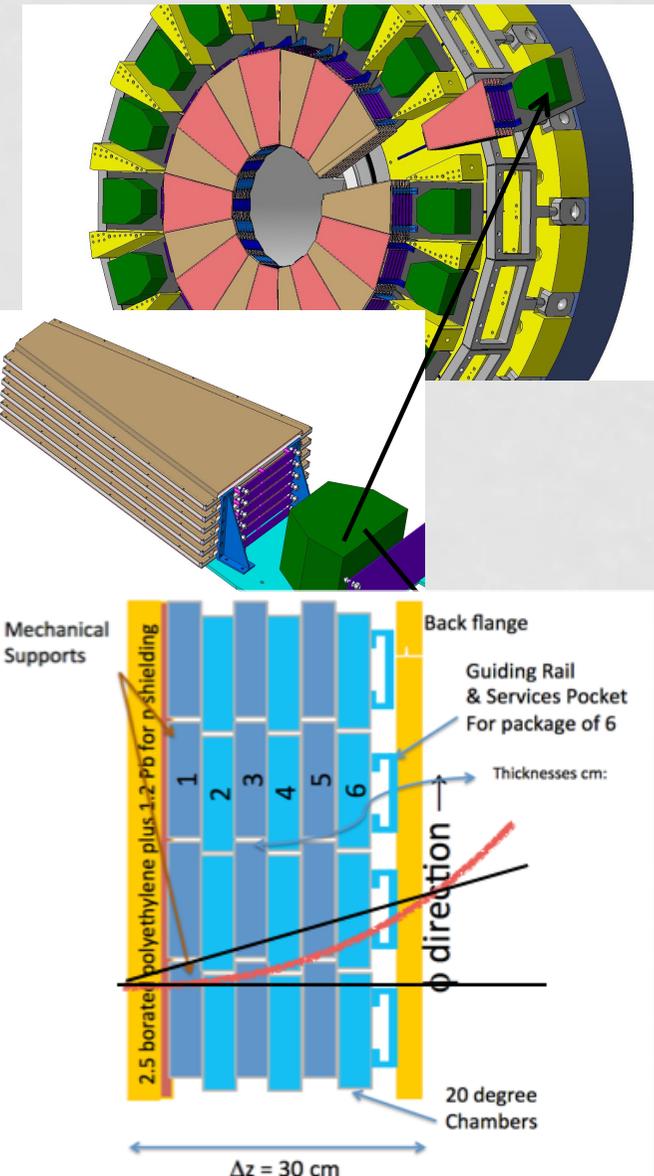

ME0 extends muon coverage down to  $\eta = 3$  to take advantage of the pixel extension

Main requirements:

- High granularity and spatial segmentation
- Multi-layered structure to reduce fakes
- Precision Timing
  - $P_T$  assignment through  $\Delta\phi$  measurement
  - Discriminate muon (segment) against neutrons (uncorr hits).
  - Reduce in-time PileUp , help vertex association

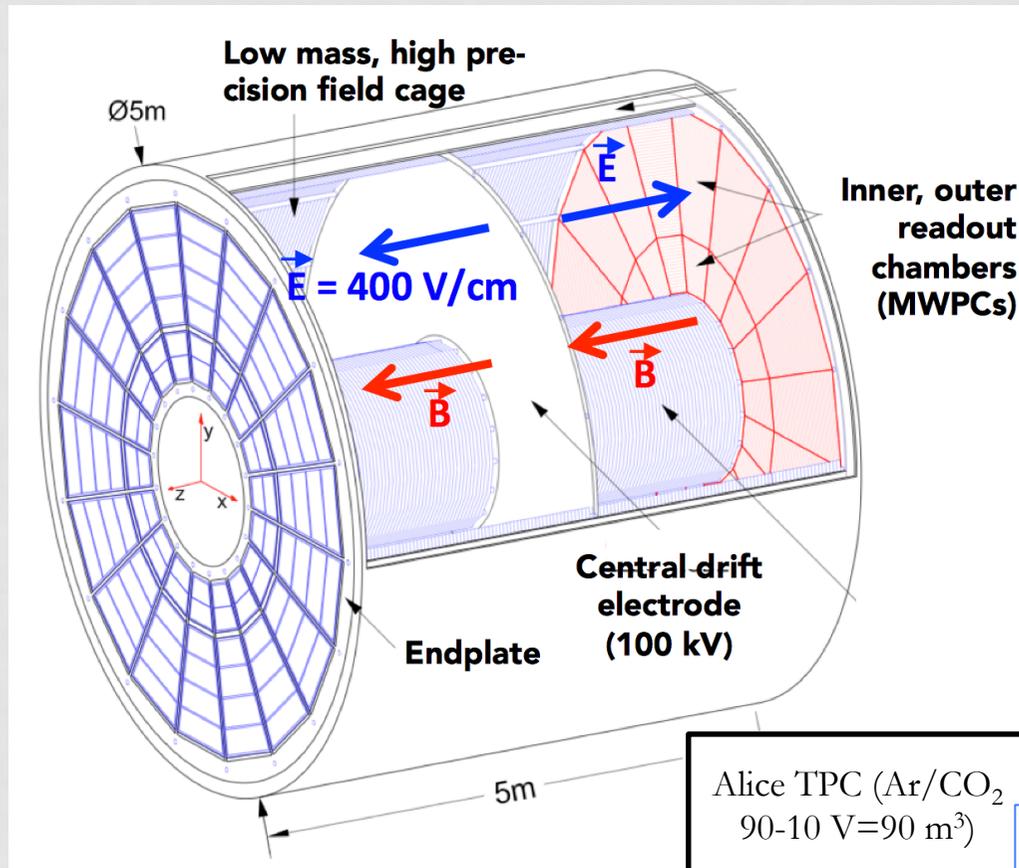

ME0 *baseline* layout consists of 216 triple-GEM chamber arranged in 36  $20^\circ$  super-module wedge each consist of **6 layers of triple GEMs (3 back-to-back)**, covering  $2 < |\eta| < 3$

Alternative technology  $\rightarrow$   $\mu$ RWell

# ALICE TPC READOUT

- Heavy Ion collisions during Run3: 500 Hz  $\rightarrow$  50 kHz collisions (1 crossing / 20  $\mu$ s)
- Important impact on the large ALICE TPC operation

Ion flow removal through the “gating grid” method is NOT possible anymore ( $\rightarrow$  280  $\mu$ s intrinsic deadtime)  
 $\rightarrow$  Continuous mode operation.

New Readout detector with:

- high gain
- good dE/dx resolution
- low IBF (Ion Back Flow)

$\rightarrow$  Large Area Quadruple-GEM

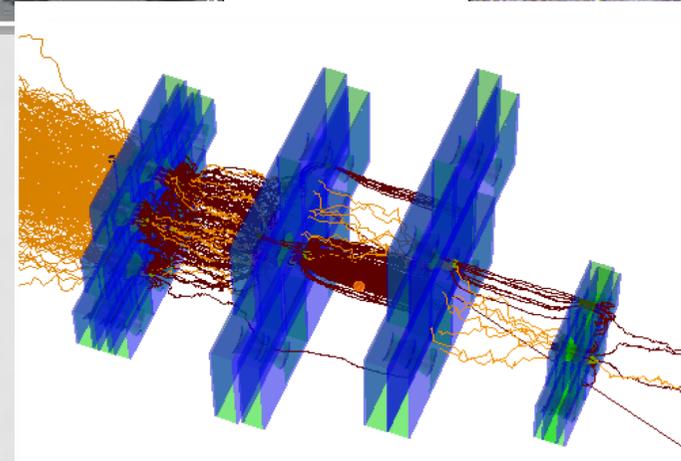

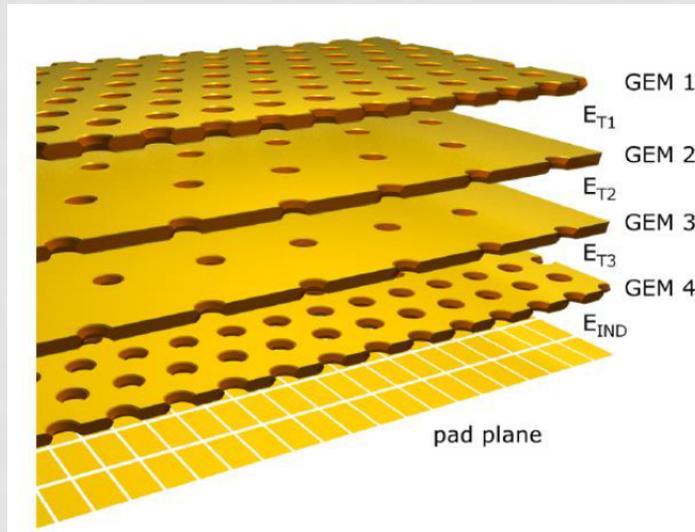

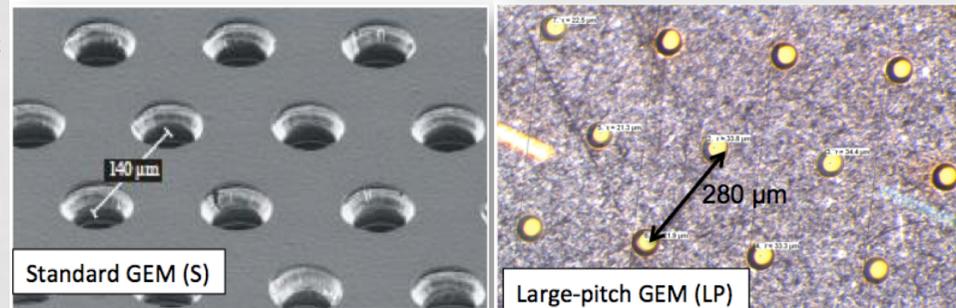

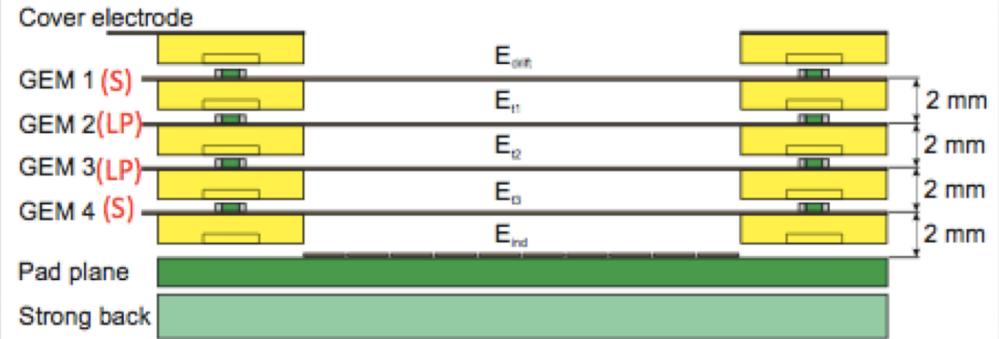

Alice TPC (Ar/CO<sub>2</sub>  
 90-10 V=90 m<sup>3</sup>)

ALICE-TDR-016 CERN-LHCC-2013-020

# ALICE QUADRUPLE-GEM - I

- **Quadruple-GEM** optimized to reduce IBF < 1% with high gain:

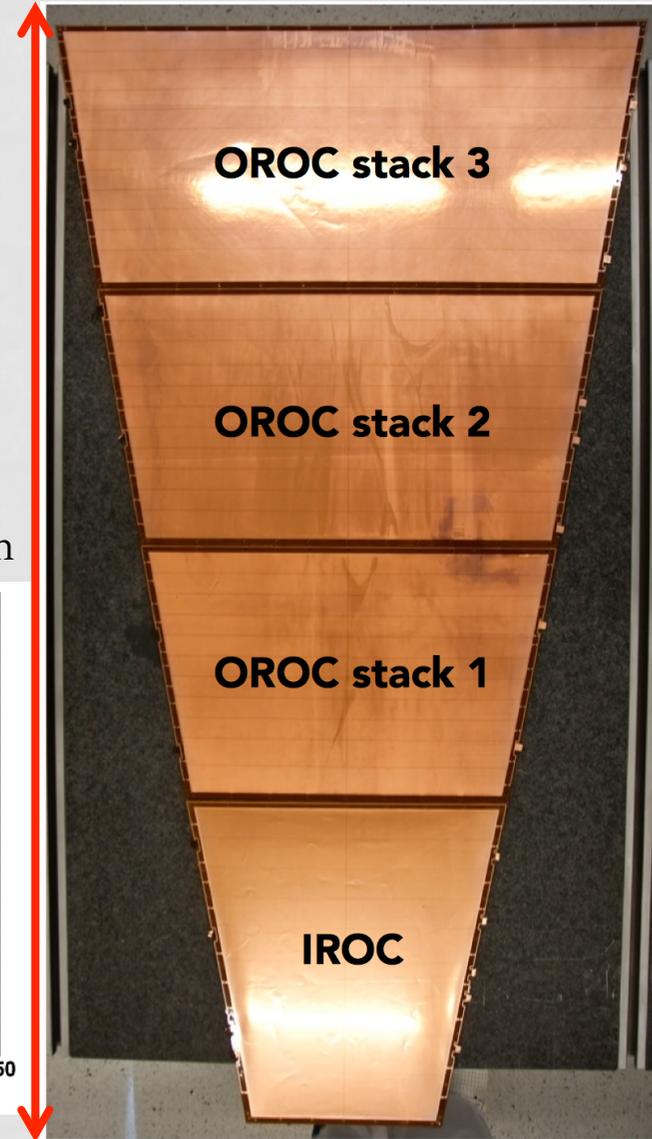

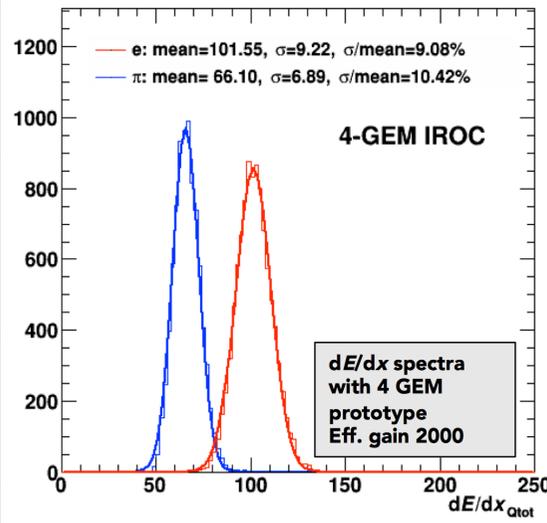

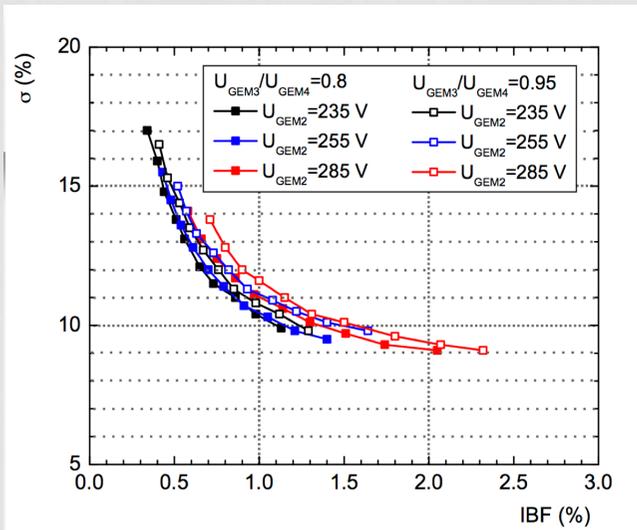

- Ne-based gas mixture:
  - Ne-CO<sub>2</sub>-N<sub>2</sub> (90-10-5)
- Standard and Large-Pitch GEMs
- Most of the gain in the last stage
- Few mm pads → drift time and charge measurement

# ALICE QUADRUPLE-GEM - II

- 72 Large area chambers: 0.6 m<sup>2</sup>, 0.2 m<sup>2</sup>
  - Single-mask technology exploited
- Results on first prototypes:
  - Gain  $\approx$  2000
  - $\sigma_x \approx \sigma_y \approx 1$  mm ,  $\sigma_z \approx 3$  mm
  - $\sigma(dE/dx) \approx 12\%$  <sup>55</sup>Fe
  - IBF < 1%

164 cm

# LHCB PROSPECTS

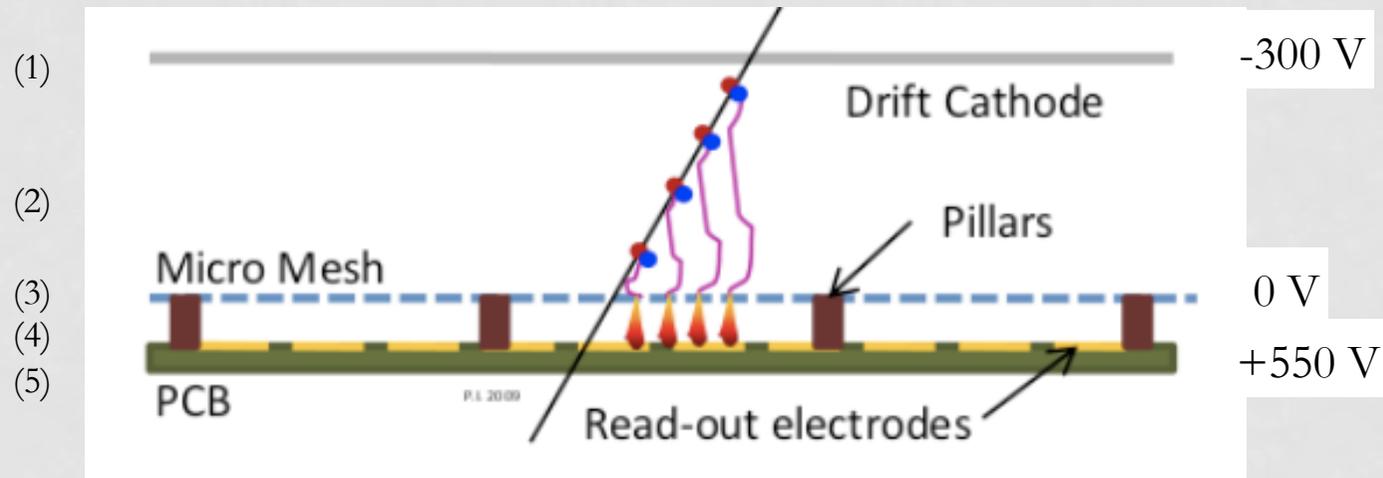

- Still under discussion in the collaboration
- Main points:
  - Probably remove M1 chambers
  - Additional small chambers ( $30 \times 30 \text{ cm}^2$ ) for triggering in the huge rate regions (up to  $0.5 \text{ MHz/cm}^2$ ) M2
  - Time resolutions below 5 ns required
    - GEM with  $\text{CF}_4$  based gas mixtures
    - $\mu\text{RWell}$  also is a possible choice to exploit the optimal time resolution for triggering purposes.

BUT the very high rate is in conflict with high resistivity.

# MICROME GAS

# MICROMEAS: PRINCIPLE OF OPERATION - I

First proposed by Y.Giomataris, NIMA 376 1 (1996) 25

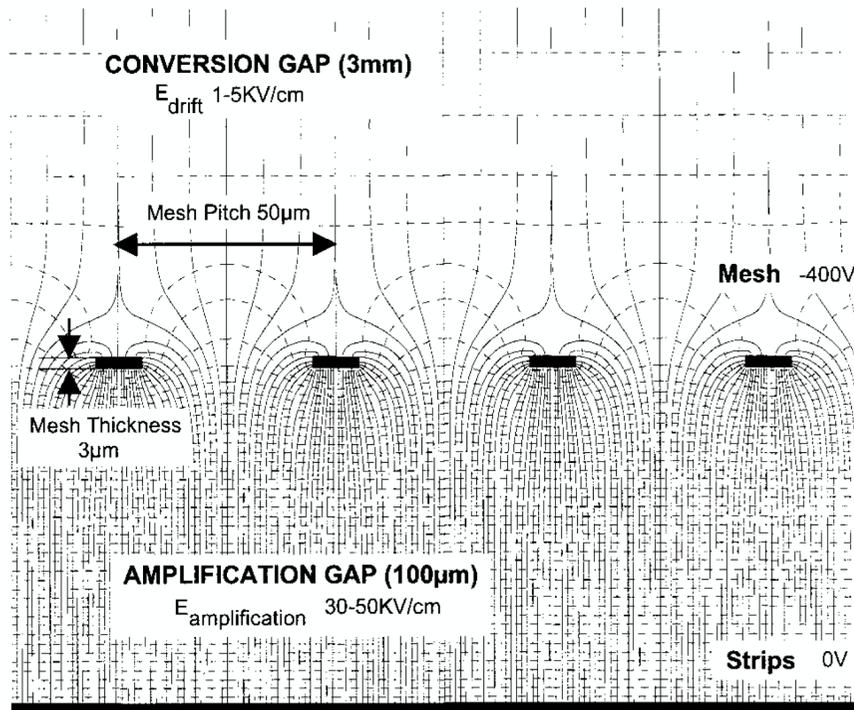

Detector components (the quoted numbers refer to the ATLAS project):

- (1) Planar metallic cathode
- (2) Gas gap (5 mm) with low electric field (0.6 kV/cm): conversion and electron drift
- (3) Thin metallic mesh standing on “pillars” (128 μm high)
- (4) 128 μm gap with high electric field (40÷50 kV/cm): avalanche
- (5) Segmented anode with read-out strips ( $\approx 400 \mu\text{m}$  pitch) on Printed Circuit Board (PCB).

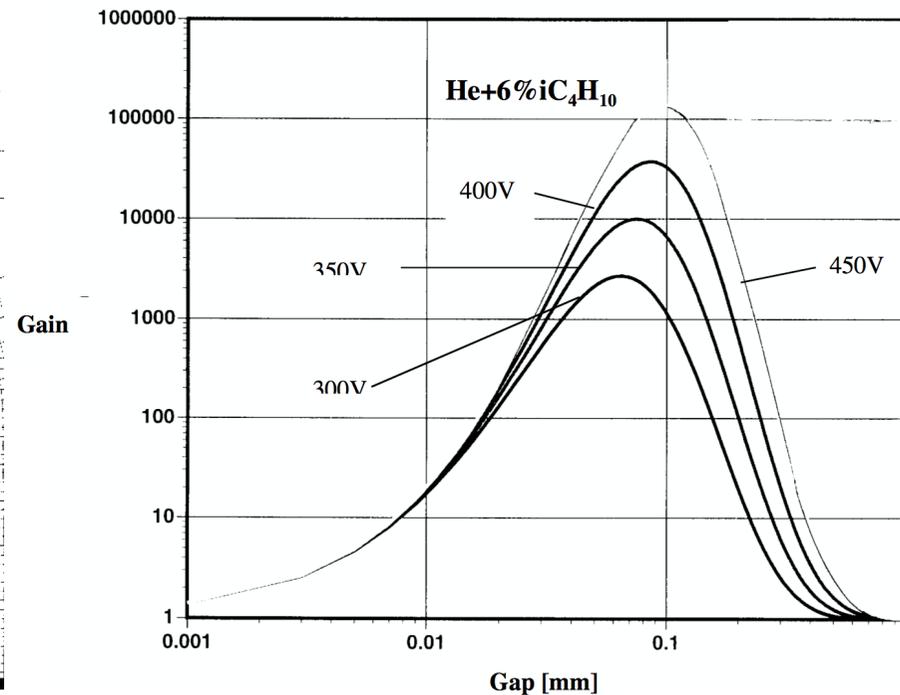

$$\text{Maximum drift time} = \text{gap size} / v(\text{drift}) = 5 \text{ mm} / 50 \mu\text{m/ns} = 100 \text{ ns}$$

# MICROMEKAS: PRINCIPLE OF OPERATION - II

Electric field lines in the mesh region

Gain vs. gap size curves

Huge electric field ratio:

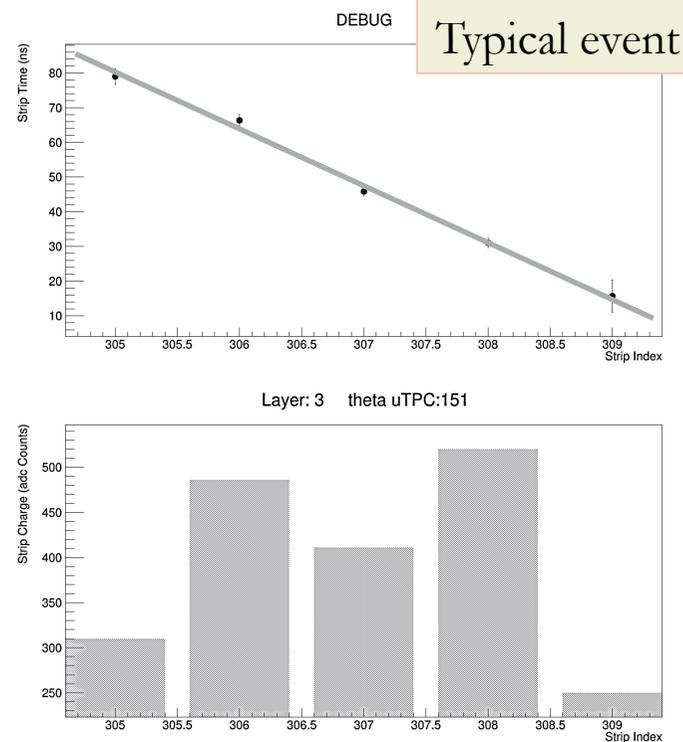

→ The mesh is “transparent” for drift electrons

→ Avalanche ions almost fully collected by the mesh (within  $\approx 100$  ns); negligible IBF

Gain “Plateau” ( $10^4 \div 10^5$ ) around  $d = 100 \mu\text{m}$

# MICROMEGAS: PROTOTYPES PERFORMANCE - THE MTPC

10x10 cm<sup>2</sup> prototypes built and tested at CERN (MAMMA collaboration)

For each strip, are measured:

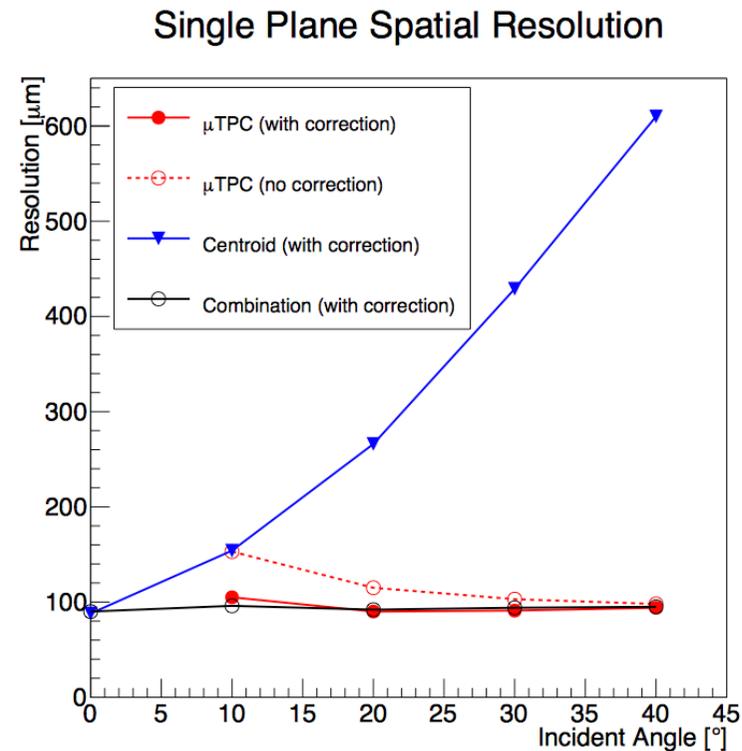

- charge
- time

→ Charge centroid

→  $\mu$ TPC (position and angle)

03/04/17

Space resolution measured on Test-Beam

Important point: good measurement also for tracks at an angle ( $\approx 100 \mu\text{m}$  for  $8 < \theta < 32^{\circ}$ )

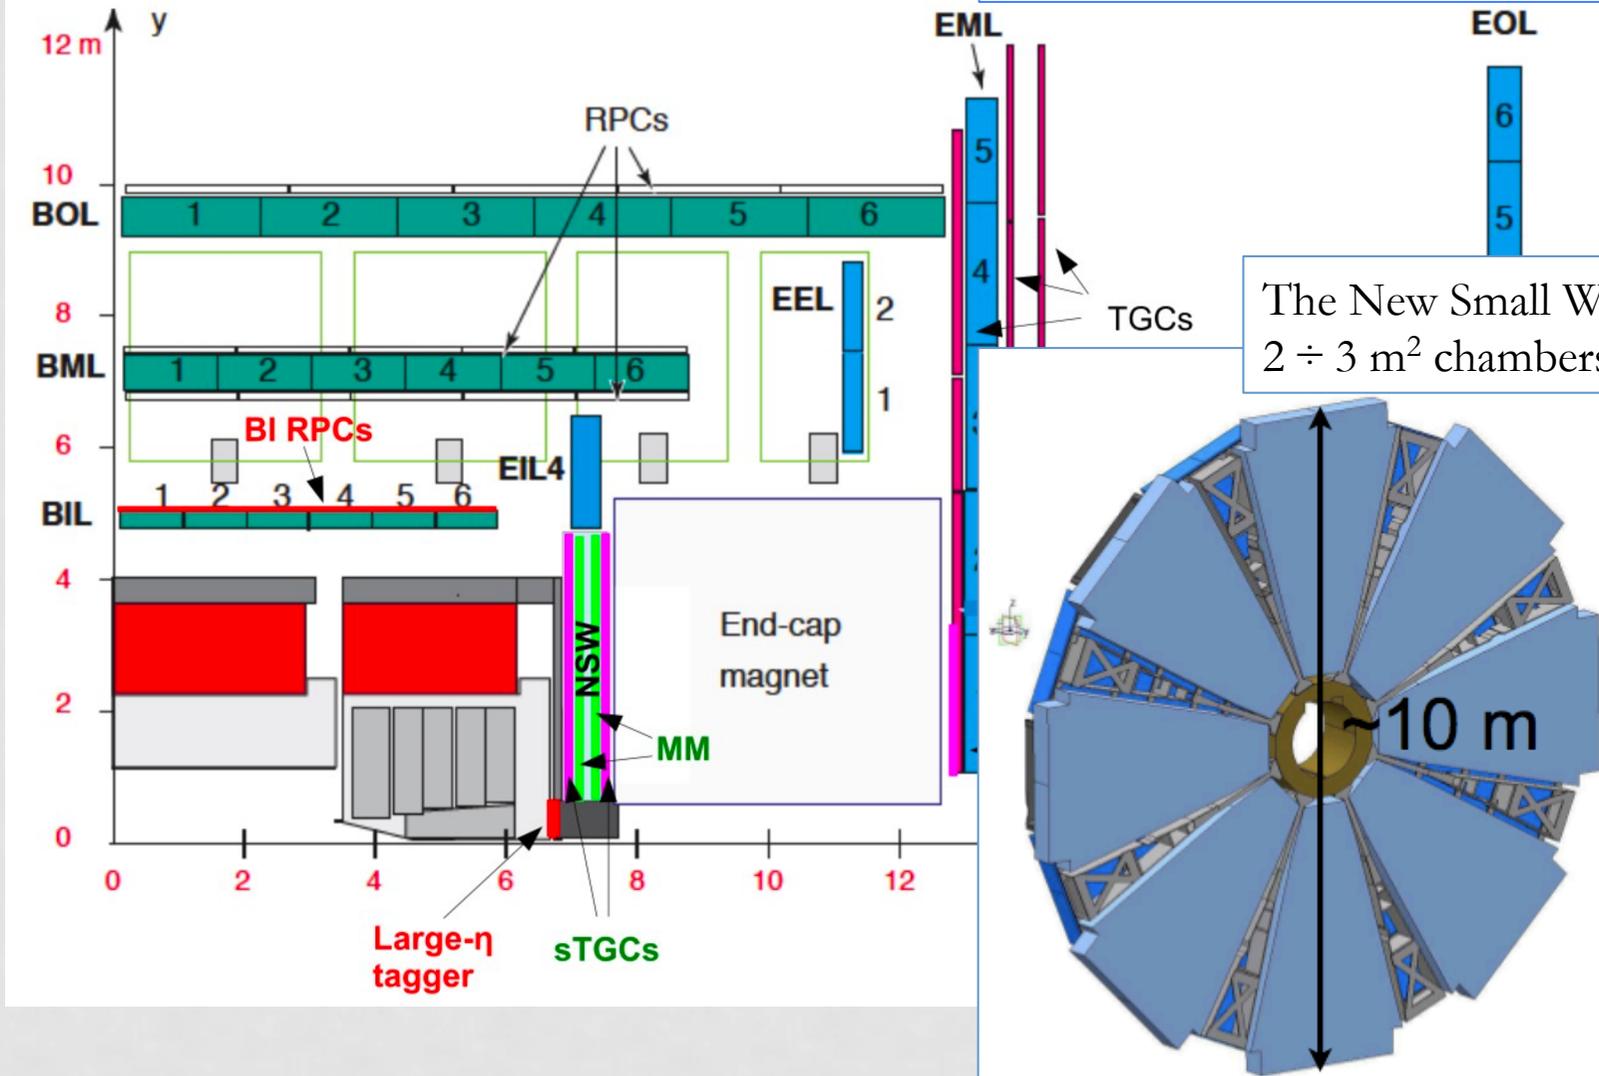

→ good for ATLAS Muons !

Status of the art of the new generation of  
MPGD detectors

22

# ATLAS: MUON FORWARD UPGRADE

ATLAS\_TDR-020 LHCC-2013-006

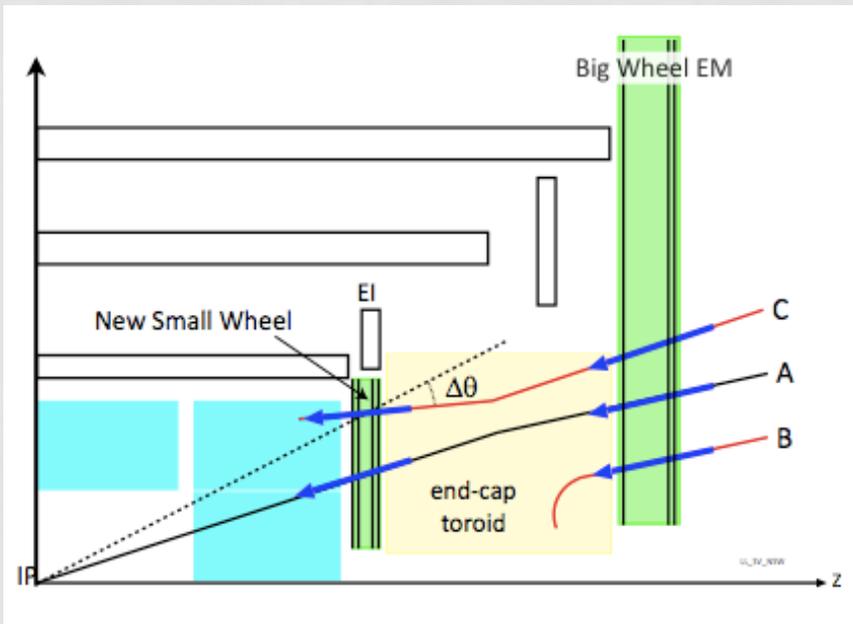

# ATLAS NSW - MOTIVATIONS

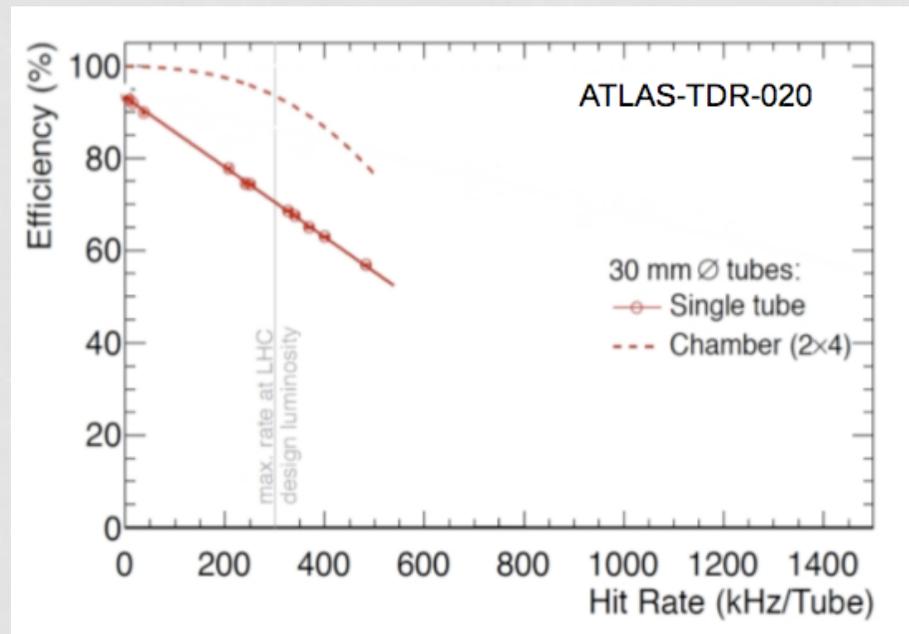

Let's consider the ATLAS forward muon case

Endcap muon trigger dominated by *fake muons*  
 →  $R(p_T > 20 \text{ GeV}) = 60 \text{ kHz}$  (@  $3 \times 10^{34}, 14 \text{ TeV}$ )  
 A factor  $> 3$  reduction → “pointing trigger”  
 allows to eliminate 90% of the fakes  
 →  $R(p_T > 20 \text{ GeV}) = 21 \text{ kHz}$  (@  $3 \times 10^{34}, 14 \text{ TeV}$ )  
 Compatible with allowed bandwidth

MDT precision chambers:  
 Beyond project luminosity → *efficiency loss*  
 → “Tube size”  $\approx 3 \text{ cm} \times 1 \text{ m} \times 750 \text{ ns}$ ;  
 → @  $7 \times 10^{34}, 14 \text{ TeV}$  →  $\approx 4 \text{ kHz/cm}^2$   
 $> 1 \text{ MHz/Tube} \approx 1 / 750 \text{ ns}$   
 $> 50\%$  drop in chamber efficiency

→ Accept **topologies A** reject **B / C**

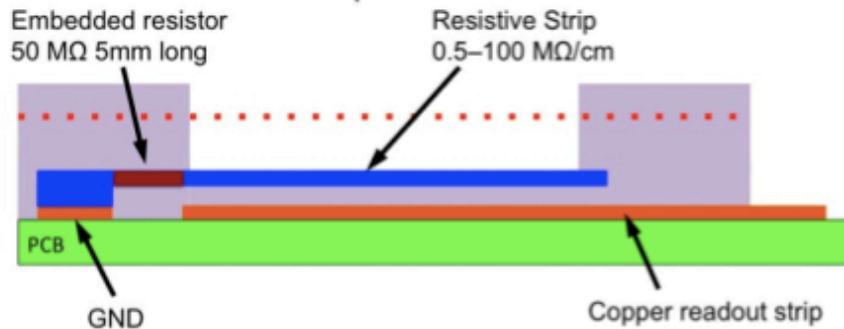

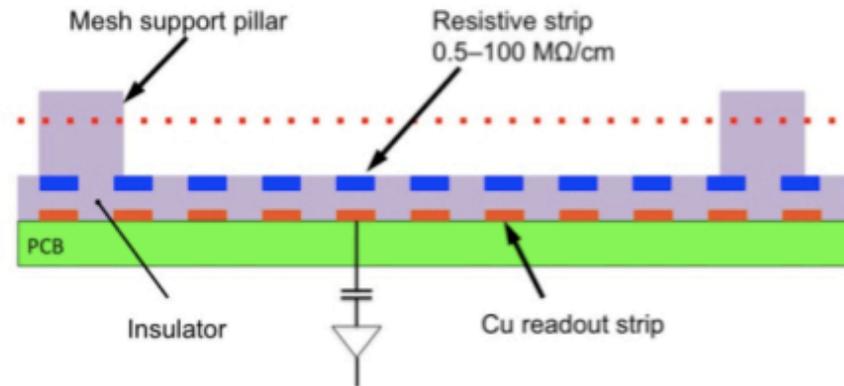

# MICROMEAS FOR ATLAS NSW - I

*High expected rate:* discharge probability to be reduced by maintaining a high gain  $\approx 10^4$

→ **Resistive strip anode**

( $\approx 20 \text{ M}\Omega/\text{cm}$ ;  $\approx 1 \text{ M}\Omega/\square$ )

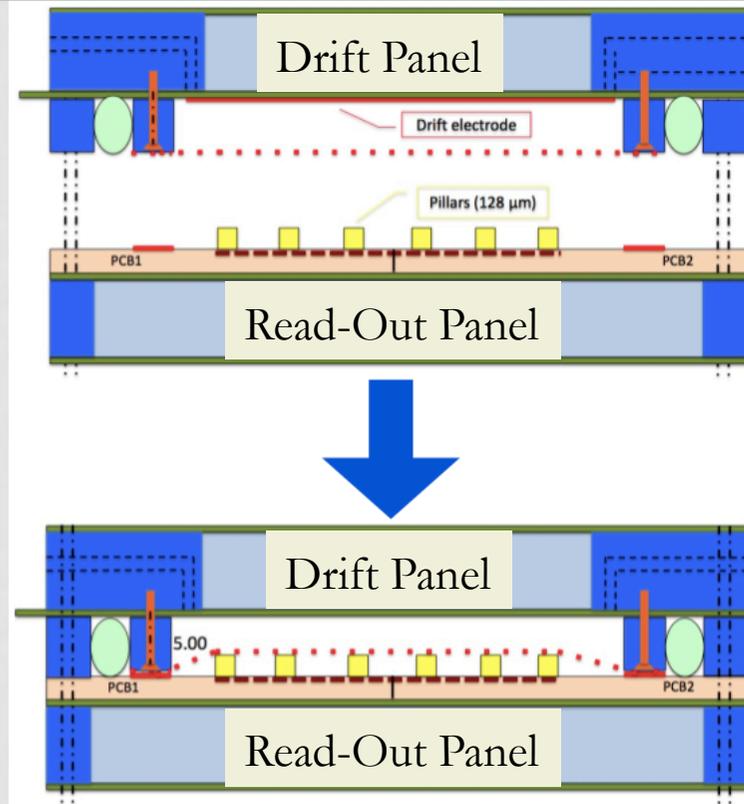

T.Alexopoulos et al. NIMA 640 (2011) 110-118

Large dimension chambers have to be built ( $2 \div 3 \text{ m}^2$ ) with challenging mechanical precisions ( $30 \div 80 \text{ }\mu\text{m}$ )

→ **new construction technique**

→ **Floating mesh**

# MICROME GAS FOR ATLAS NSW - II

The ATLAS MicroMegas chambers are organized in Q-plets:

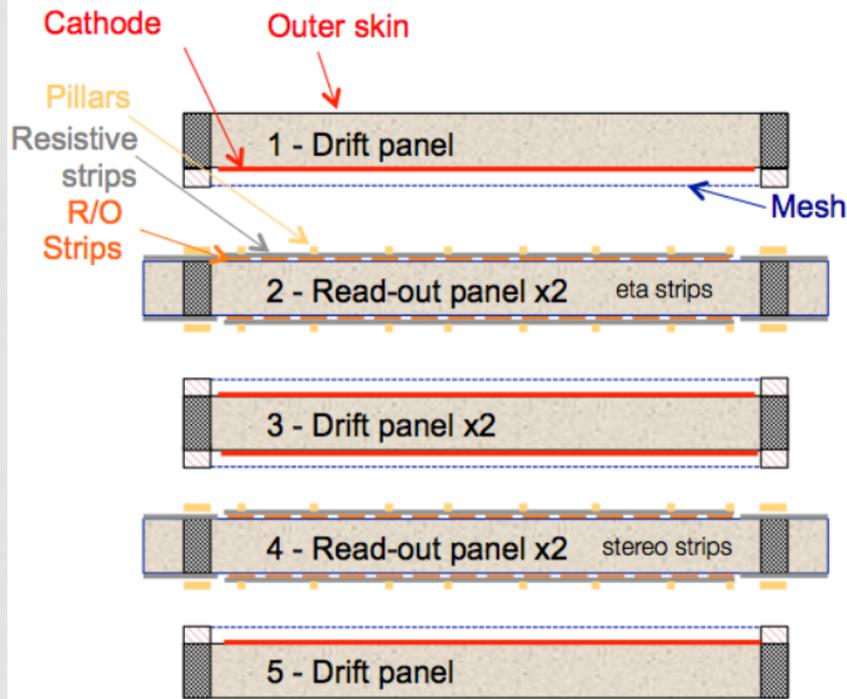

5 panels 1 cm thick 2 m<sup>2</sup> surface (planarity RMS < 40 μm)

2 RO panels (with RO PCB)

3 Drift panels + tensioned mesh

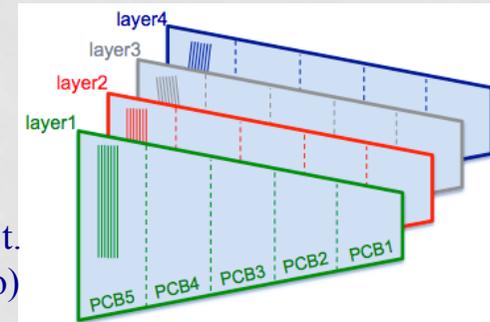

Stereo configuration to get the second coordinate at O(mm)

Operate in a moderate magnetic field (< 0.3 T)

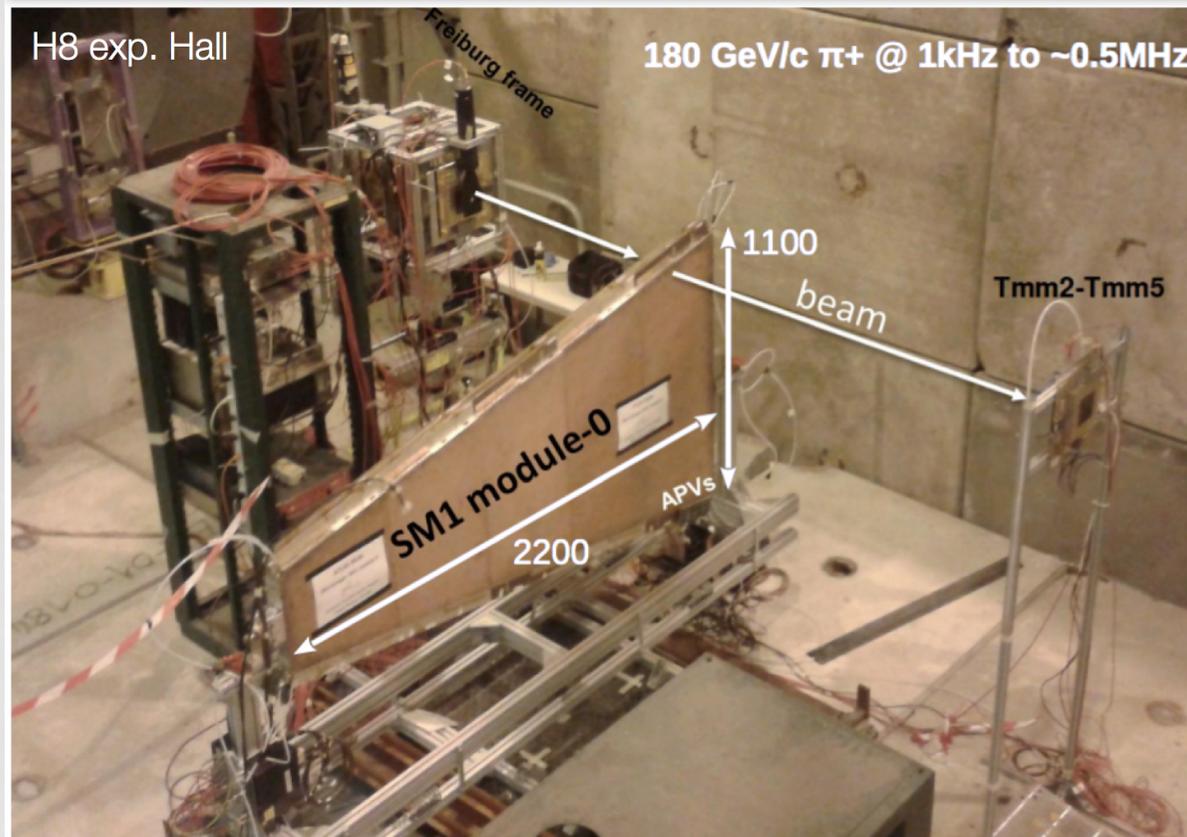

## SM1 quadruplet:

- 425 μm strip pitch
- L1 & L2 vertical strips (eta),
- L3 & L4 ±1.5° w.r.t. vertical axis (stereo)

Module0s (full size) Q-plets built in 2016  
SM1 (INFN) tested on beam → Next slide

# SM1 MODULE0 – THE TEST-BEAM

Measurements done on a 180 GeV beam in “standard” conditions

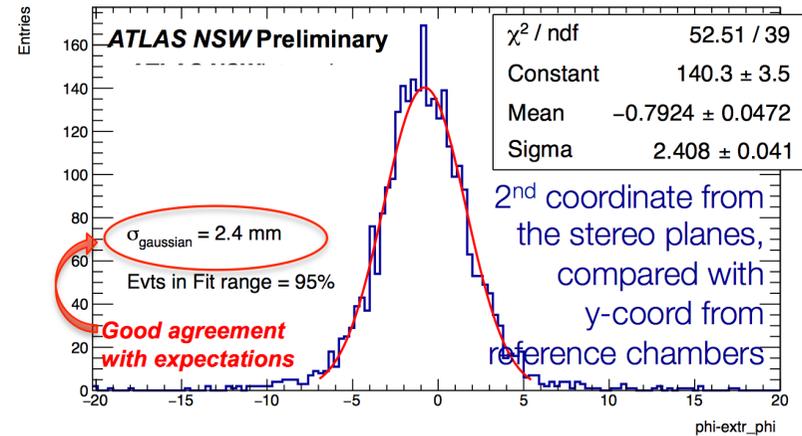

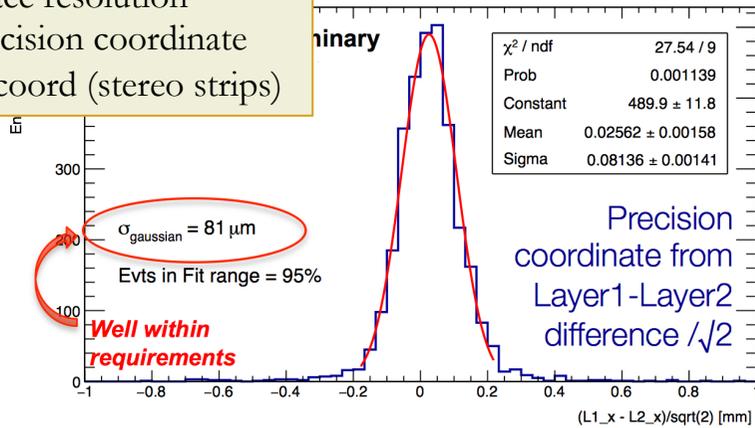

- Gas Mixture Ar/CO<sub>2</sub> (93%-7%) @ 20 l/hr
- HV(ampl) = 580 V, HV(drift) = 300 V
- FE electronics APV25

Aim: validation of the first 2 m<sup>2</sup> Q-plet

# FIRST LARGE PROTOTYPE PERFORMANCE

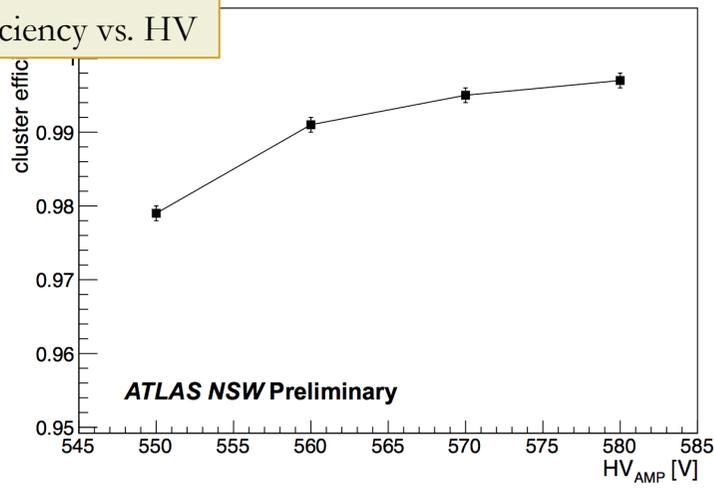

Preliminary results obtained for perpendicular tracks (charge centroid method)

Space resolution  
Precision coordinate  
2° coord (stereo strips)

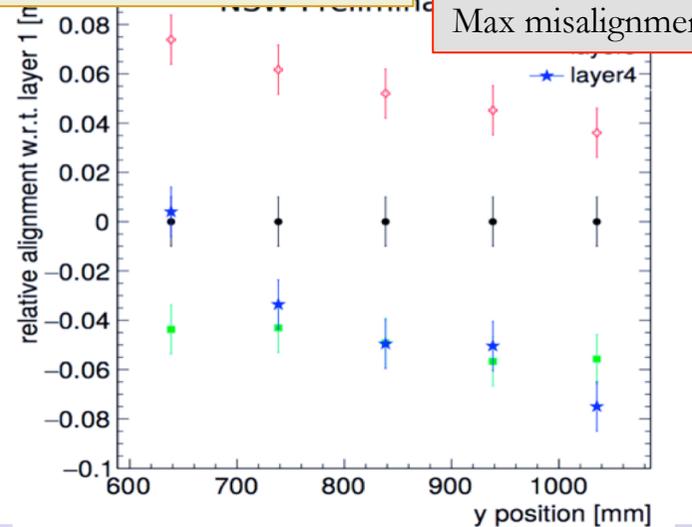

Cluster efficiency Vs Amplification HV for Layer1

Efficiency vs. HV

Alignment between strip layers

ATLAS Requirement  
Max misalignment < 60  $\mu\text{m}$

# LARGE ETA TAGGER

Very large –  $\eta \rightarrow 2.7 < |\eta| < 4$

Hit rates up to **9 MHz/cm<sup>2</sup>**

@ highest L of HL-LHC ( $\mu = 200$ )

Resolution of few 100  $\mu\text{m}$

Crucial points:

Hit granularity down to **1 mm level**

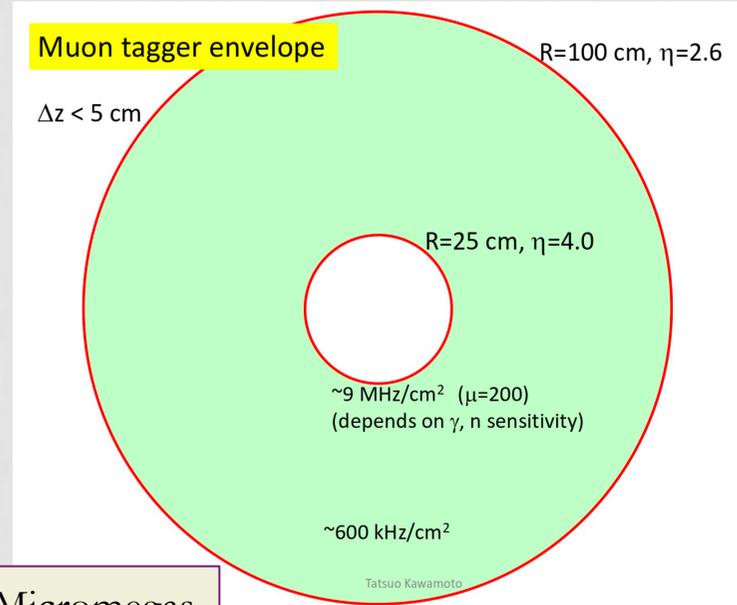

Multi-layer

**2D reconstruction**

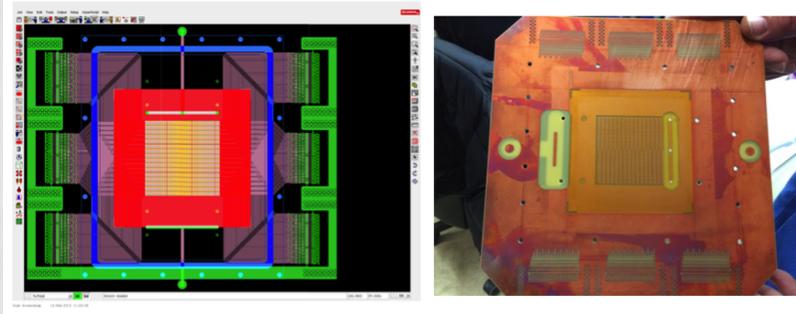

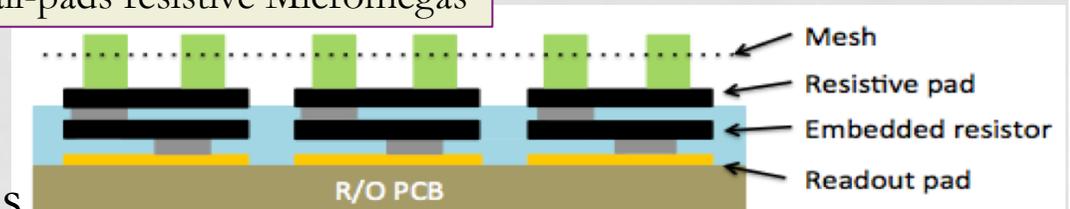

Three options are considered:

1. Small-pads resistive Micromegas
2. Micro Pixel Chamber ( $\mu$ -PIC)
3. Micro-Resistive Well ( $\mu$ RWell)

Pads with rectangular shape 0.82.8 mm<sup>2</sup>  
R&D in progress, first test-beam recently

Small-pads resistive Micromegas

# RECENT DEVELOPMENTS

# NEW DIRECTIONS

- MPGD principle of operation to obtain “triggering” and “tracking” detectors with, at the same time:
  - Stability of operation at high rates
  - Good space resolution  $O(100 \mu\text{m})$
  - **Improved time resolution  $O(\text{ns})$**
  - **Simplified construction/assembly procedures**
- Recent ideas:
  - **Micro-Resistive Well** (simplicity of construction)
  - **Fast Time Micropattern** (exploiting the possibility to reach  $O(1 \text{ ns})$  time accuracy)

# MICRO-RESISTIVE-WELL

*G. Bencivenni et al., 2015\_JINST\_10\_P02008*

“**Micromegas with a GEM foil for amplification**”..

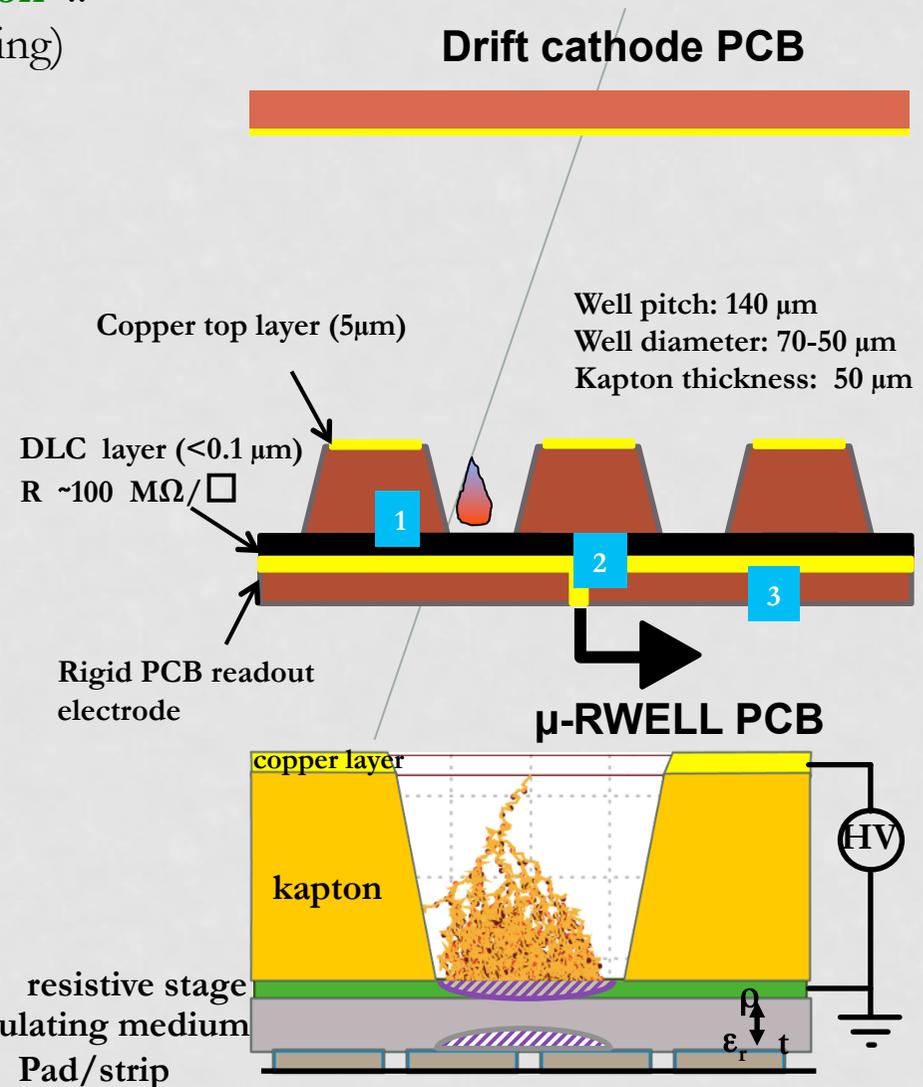

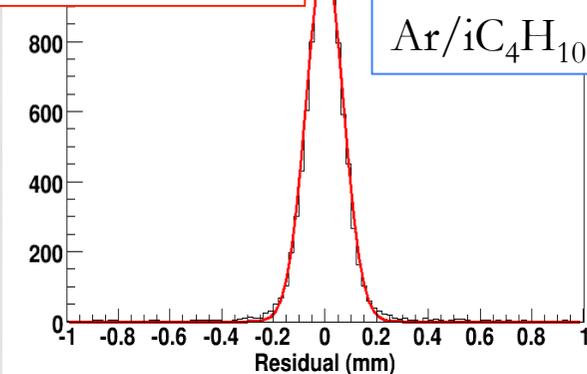

- Simple assembly procedure (no gluing, stretching)
- High-rate behaviour depends on the resistive stage (100 kHz/cm<sup>2</sup> up to 10 MHz/cm<sup>2</sup>)
- Time resolution 6 ns
- Space resolution < 100 μm

First large size prototype (GE1/1 size)  
under test, results soon

→ CMS GE2/1 and/or LHCb M2 chambers  
and/or ATLAS Large Eta Tagger

$\sigma_{RWELL} = (52 \pm 6) \mu\text{m}$   
@ B= 0T after TRKs  
contribution  
subtraction

Space resolution:  
Prototype 10x10 cm<sup>2</sup>  
Read-out through APV25  
Ar/iC<sub>4</sub>H<sub>10</sub> 90/10

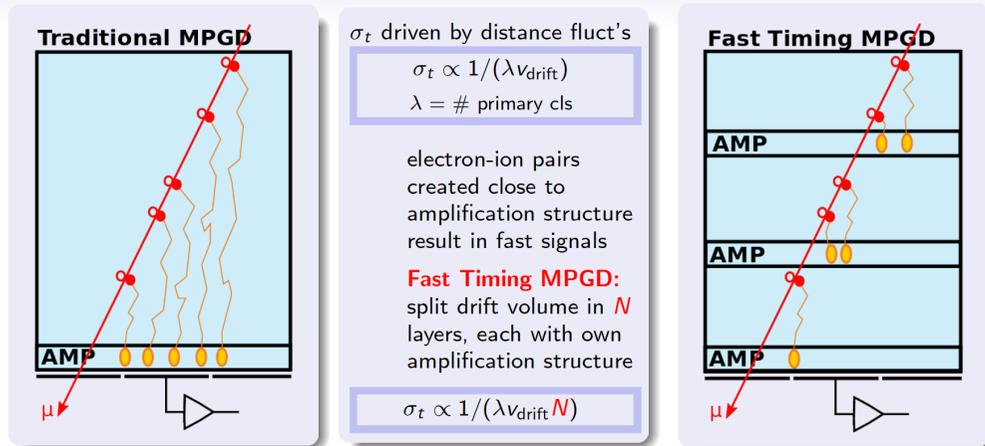

# FAST TIME MICROPATTERN

The time resolution in a MPGD depends on the fluctuation of the arrival time of the first electron

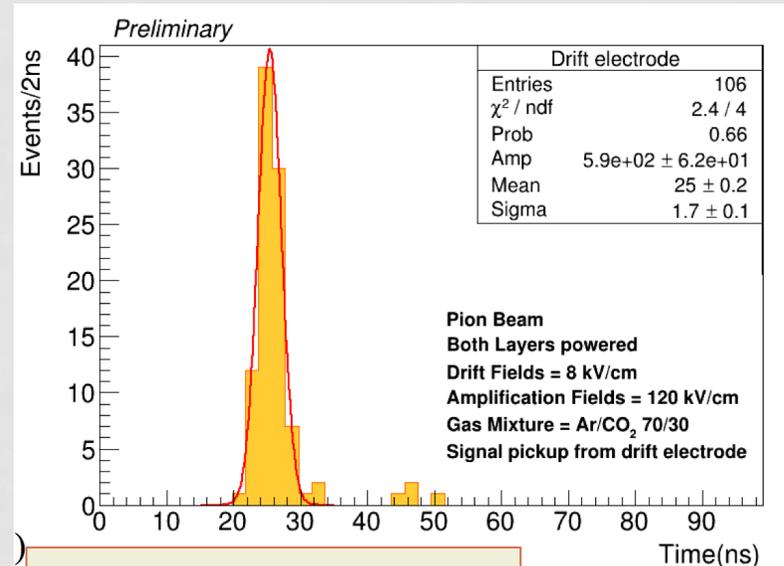

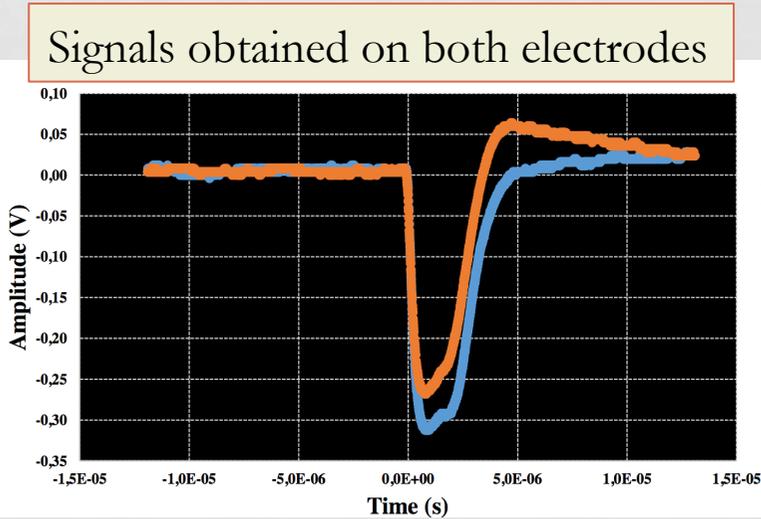

$$\sigma_t = 1 / (\lambda v_d)$$

This can be reduced by a factor  $N_D$ ,  $N_D$  being the number of independent drift-amplification stages. Resistive layers  $\rightarrow$  structure transparent to signals that can be extracted at every amplification stage

M. Maggi, A. Sharma, R. De Oliveira  
arXiv:1503.05330v1

- resistive structure  $\Rightarrow$  signal from any layer induced in readout
- time resolution should improve with  $N = \text{number of layers}$

$\sigma_t \approx 2 \text{ ns}$  with 2 stages

# SUMMARY AND CONCLUSIONS

- Starting from **LHC Run3 (>2020)** large area MPGD will be used by the LHC experiments to support the expected large particle rates.
- **GEM technology** will be widely used (Alice, CMS, LHCb)
- **MicroMegas technology** will be used by ATLAS reaching the largest dimensions (up to 3 m<sup>2</sup> chambers)
- This is a challenge under several points of view
- In the meantime **new MPGD concepts** are developed
