# Particle Physics - Chapter 6 The Standard Model

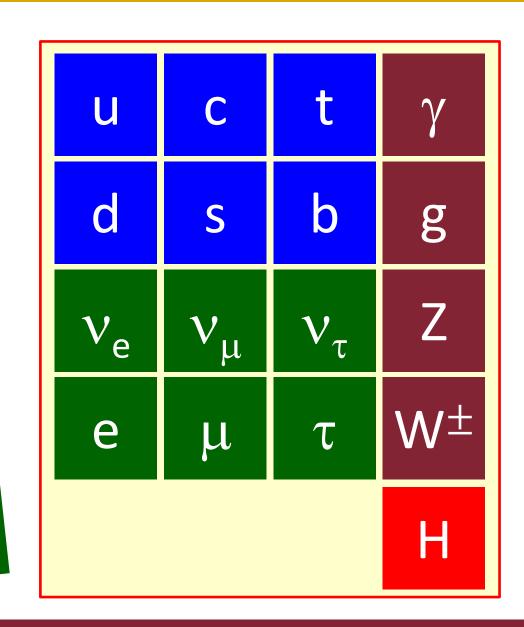

AA 18-19

# 6 - The Standard Model

- The Electroweak Theory
- 2. Electroweak results
- **QCD**
- **Strong interactions**
- Hadrons in the final state
- **QCD** results
- 7. "Grand unification bSM"?

The style of this chapter depends on our CdL:

- the electroweak part is an overlap with
- previous semester  $\rightarrow$  just for reference;
- the QCD part is different: still amateurish, but I'm the first to tell you;
- the Higgs part is in § LEP and § LHC.

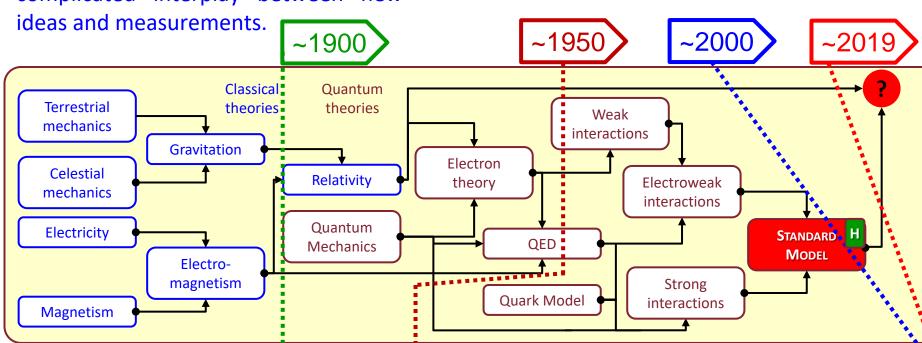

#### **The Standard Model**

- The name <u>SM</u> (not a nice name)
   designates the theory of the Electromagnetic, Weak and Strong interactions.
- The theory has grown in time, the name went together.
- The development of the SM is a complicated interplay between new ideas and measurements.

- Many theoreticians have contributed: since the G-S-W model is at the core of the SM, it is common to quote them as the main authors.
- The little scheme [BJ] of its time evolution may help (missing connections, approximations, ...).

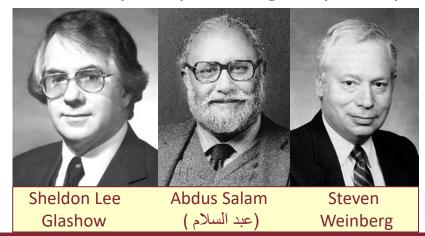

# the electroweak theory

- Glashow (1961), Salam (1964), Weinberg (1967) provided the main ingredients for the unification of weak and electromagnetic interactions.
- The fundamental interactions are described by field theories, invariant under local gauge transformations.
- Technically, by a Lagrangian  $\mathscr{L}$ , invariant under the appropriate symmetries.
- The symmetries correspond, via the Noether theorem, to the conservation laws of the Theory.
- The conservation laws are local [i.e. in a given space-time point]: electric charge is the usual example of such a quantity.
- In the Standard Model, the electromagnetic and weak interactions (both CC and NC) are related to the symmetry group  $SU(2) \otimes U(1)$ .

- The parameters of the theory controls all the phenomena: "few" independent masses and couplings for the full theory.
- The dynamics is fully regulated: (e<sup>±</sup>, μ<sup>±</sup>, v) DIS, e<sup>+</sup>e<sup>-</sup> processes (LEP), IVB and Higgs production and decay (SppS, LHC) are fully described by the e.w. Theory.
- Among the successful predictions <u>neutral currents</u>,  $\underline{W}^{\pm}$ ,  $\underline{Z}$ , <u>Higgs</u>.
- [in the '60s/'70s no strong interactions theory, but now QCD occupies the role.]
- [as of today, no quantum gravity theory.]

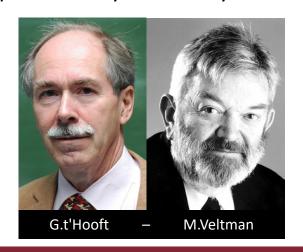

# the e.w. theory: properties

- Any theory (including the e.w.) has to be free from logical and mathematical inconsistencies.
- In mathematical terms, it MUST be renormalizable, i.e. it must exist a mathematically correct procedure, that eliminates the infinities that arise in calculations of physical observables, such as cross sections and decay rates.
- To achieve this objective, the e.w. 

   must not contain explicitly mass terms;
   i.e., at the 

   level, both the Gauge bosons (the "fields") and Fermions (the "matter") must be massless.
- The proof of the renormalizability of the theory was provided by 't Hooft and Veltman (in 1971, Nobel Prize in 1999).
- The masses are then generated in the theory, without destroying the

- renormalizability, with the mechanism of spontaneous symmetry breaking, usually called <u>Higgs mechanism</u>, proposed by Englert & Brout (1964), Higgs (1964) and Gularnik, Hagen & Kibble (1964).
- The mechanism predicts the existence of (at least) one scalar, the <u>Higgs boson</u> H.
- The values of the fermion masses are left as <u>free parameters</u>; however, once they are fixed, all the couplings of the H boson to the other bosons and fermions are predicted by the theory.

# the e.w. theory: I<sub>w</sub>, Y

The properties of the gauge bosons  $W^{\pm}$ , Z and  $\gamma$  come out from the theory.

- The fundamental representation of SU(2)
   ⊗ U(1) is given by three [SU(2)] and one [U(1)] Gauge fields.
- The quantity called "weak isospin" I<sub>w</sub> [here called simply "isospin"(\*)] belongs to the SU(2) sector.
- For U(1), there is the "weak hypercharge"
   Y<sub>w</sub> [here "hypercharge"].
- All the members of the same isospin multiplet have the same hypercharge.
- Similarly to the flavor case, the hypercharge is defined as twice the difference between the electric charge and the third component of the isospin:

$$Y_W \equiv 2 (Q - I_{Wz}).$$

The triplet of fields corresponding to SU(2) is called W = (W<sub>1</sub>, W<sub>2</sub>, W<sub>3</sub>). The fields W

- have  $I_W = 1$  and  $Y_W = 0$ . They interact with the weak isospin of the particles.
- The field corresponding to U(1) is called **B**. Its isospin, electric charge and hypercharge are zero. It interacts with the weak hypercharge of the particles.
- These four fields (W<sub>i</sub>, B) are NOT the physical fields which mediate the interactions.
- The CC weak interactions are mediated by  $W^{\pm}$ , which are linear combinations of  $W_1$  and  $W_2$ .
- The photon and the Z, mediators of the electromagnetic and NC weak interactions, are linear combinations of W<sub>3</sub> and B.

大

<sup>(\*)</sup> Notice that the weak isospin and hypercharge do NOT have any dynamical relation with those defined in precedence for the hadrons, although their mathematical properties are the same.

# the e.w. theory: fermions

The value of  $I_W$  and  $Y_W$  of the particles depends on the fact that the  $W^{\pm}$ , the mediators of the CC, are coupled only to states with negative chirality.

<u>The leptons</u>. In each family there are two left-handed leptons in a  $I_w = \frac{1}{2}$  doublet:

$$\begin{split} I_W &= 1/2, \ I_{Wz} = + 1/2 \ : \ \nu_{eL}, \ \nu_{\mu L}, \ \nu_{\tau L}; \\ I_W &= 1/2, \ I_{Wz} = - 1/2 \ : \ e^-_L, \ \mu^-_L, \ \tau^-_L. \end{split}$$

- the v's have a (small but non-zero) mass and mix together (mixing matrix  $3\times3$ );
- unlike the charged currents, the neutral currents also interact with the charged right-handed fermions, but NOT with right-handed neutrinos;
- the right-handed charged lepton of each family is an isospin singlet  $(I_W = 0)$ :

$$I_{W} = 0$$
,  $I_{Wz} = 0$ :  $e_{R}^{-}$ ,  $\mu_{R}^{-}$ ,  $\tau_{R}^{-}$ .

• right-handed v's DO NOT EXIST [more

precisely, if existing, they have  $(I_W = Y_W = 0)$  and do NOT interact with anything except possibly through <u>gravity</u>].

The quarks. Their structure is similar, apart from a different mixing (the CKM matrix) and the color:

- The W<sup>±</sup> is universally coupled with the CKM-rotated states d', s' and b'.
- [three isospin doublets, one for each family] × [three colors] = nine doublets :

$$I_{W} = \frac{1}{2}$$
,  $I_{Wz} = +\frac{1}{2}$  :  $u_{L}$ ,  $c_{L}$ ,  $t_{L}$ ;  $I_{W} = \frac{1}{2}$ ,  $I_{Wz} = -\frac{1}{2}$  :  $d'_{L}$ ,  $s'_{L}$ ,  $b'_{L}$ ;

• the singlets (18 in total) are:

$$I_W = 0 : d_R, u_R, s_R, c_R, b_R, t_R;$$

 for NC, the quark mixing is irrelevant; therefore we can study the interactions of the "non-rotated" states.

# the e.w. theory: a remark on v's

#### Some alternative hypotheses on v's:

- a) Dirac particles, charge=0, spin=½, mass=0, helicity = −1, partners of charged leptons:
   → v's do not mix;
- b) as (a), but  $m_{v's} > 0$ , although <u>very</u> small:
  - → v's can mix, define the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) mixing matrix;
  - → helicity NOT intrinsic, depends on Lsystem [but see comment];
  - $b_1$ ) PMNS diagonal  $\rightarrow v's$  do not mix;
  - b<sub>2</sub>) PMNS NOT diagonal  $\rightarrow$  <u>v's do mix</u>;
- c) any hypothesis bSM (e.g. Majorana v's).

# in [MQR] and [IE], (a) and (b) are called "Weyl $\nu$ 's", while "Majorana $\nu$ 's " are in (c).

#### Results:

- (a) believed to be correct for most of the XX century; <u>falsified</u> in 1998 by discovery of v-oscillations [v-o.];
- (b<sub>1</sub>) [ugly] falsified by v-0.;
- (b<sub>2</sub>) <u>current working hypothesis</u> [because minimal extension of the SM]; however it looks unlikely to most [???] physicists;
- (c) <u>much appreciated</u>; however, as of today, no data supports it (many new ongoing experiments: <u>good luck !!!</u>).

#### Comment:

- v oscillations (→ mixing) appear only in astro-physical or long-baseline experiments;
- in all other experiments, data (<u>until today</u>) consistent with (a);
- no contradiction:  $(m_{v's} \ll E_{v's}) \rightarrow (v's \text{ ultra-relativistic}) \rightarrow (a) \text{ good approx. of (b)}.$

#### **Conclusion** (as of today):

- (at least two) ν's have mass > 0;
- v's can and do oscillate (PMNS  $\neq 1$ );
- for most exp., approx.  $m_{v's}$ =0, no-oscillation, fixed helicity (-1 for v, +1 for  $\bar{v}$ );
- hope for new exp., or more precise data.

# the e.w. theory: antiparticles

- <u>The antiparticles</u>. For each particle, there exists an antiparticle, with opposite quantum numbers.
- In the lepton sector, for CC there are the following three doublets of antileptons :

• Plus the following singlets:

$$I_{W} = 0$$
,  $I_{Wz} = 0$  :  $e_{L}^{+}$ ,  $\mu_{L}^{+}$ ,  $\tau_{L}^{+}$ .

- For the  $\bar{\nu}$ 's, the same rules apply as for  $\nu$ 's.
- In the antiquark sector, three doublets of isospin and six singlets for each family (9 plus 18 in total):

$$\begin{split} I_{W} &= \frac{1}{2}, \ I_{Wz} &= + \frac{1}{2} \ : d'_{R}, \bar{s}'_{R}, \ \bar{b}'_{R}; \\ I_{W} &= \frac{1}{2}, \ I_{Wz} &= - \frac{1}{2} \ : \bar{u}_{R}, \ \bar{c}_{R}, \ \bar{t}_{R}; \\ I_{W} &= 0 \ : d_{L}, \ \bar{u}_{L}, \ \bar{s}_{L}, \ \bar{c}_{L}, \ \bar{b}_{L}, \ \bar{t}_{L}. \end{split}$$

#### P.A.M. Dirac, 1933 Nobel Lecture:

"If we accept the view of complete symmetry between positive and negative electric charge so far as concerns the fundamental laws of Nature, we must regard it rather as an accident that the Earth (and presumably the whole solar system), contains a preponderance of negative electrons and positive protons.

It is quite possible that for some of the stars it is the other way about, these stars being built up mainly of positrons and negative protons. In fact, there may be half the stars of each kind. The two kinds of stars would both show exactly the same spectra, and there would be no way of distinguishing them by present astronomical methods."

Great !!! But presently we know much more (more precisely, we ignore much more).

Find where we "improved" in the last 85 years.

×

# the e.w. theory: summary of q.n.

	Spin	I <sub>w</sub>	I <sub>Wz</sub>	Y <sub>W</sub>	Q (*)
VeL	1/2	1/2	+½	-1	0
<b>6</b> _ <sup>r</sup>	1/2	1/2	-1/2	-1	-1
<b>e</b>	1/2	0	0	-2	-1
u <sub>L</sub>	1/2	1/2	+½	+1// <sub>3</sub>	2/3
d' <sub>L</sub>	1/2	1/2	-1/2	+1// <sub>3</sub>	<b>−½</b>
$u_R$	1/2	0	0	+4/3	2/3
d <sub>R</sub>	1/2	0	0	<b>-</b> <sup>2</sup> / <sub>3</sub>	<b>−½</b>
W <sup>+</sup>	1	1	+1	0	+1
W-	1	1	-1	0	-1
Z	1	1,0	0	0	0
γ	1	1,0	0	0	0
н	0	0	0	0	0

- Weak isospin (I<sub>W</sub>) and weak hypercharge (Y<sub>W</sub>) are conserved in all known interactions.
- I<sub>W</sub> and Y<sub>W</sub> have nothing to do with those of hadrons.
- $I_W$  is the source of the weak charged fields  $W^{\pm}$ .
- $Y_W$  and  $I_{Wz}$  are the sources of the weak neutral field Z and of the e.m. field  $\gamma$ .
- The L(eft) components of the spinors have I<sub>W</sub>
   ≠ 0; they emit and absorb W<sup>±</sup>.
- The R(ight) components have  $I_W = 0$ ; they do not emit or absorb  $W^{\pm}$ .
- Both components have Y<sub>W</sub> ≠ 0; they emit and absorb Z.
- the  $v_R$  have  $I_W = 0$  and  $Y_W = 0$ ; they do not exist or are not observable (in the m=0 limit).

 $<sup>(*)</sup> Q = I_{wz} + \frac{1}{2} Y_{w}.$ 

# the e.w. theory: the IVBs W/Z

**The field W**<sub> $\mu$ </sub> = (W<sub> $\mu$ 1</sub>, W<sub> $\mu$ 2</sub>, W<sub> $\mu$ 3</sub>) is a 4-vector in the space-time<sup>(\*)</sup>, and a vector in the space of the weak isospin I<sub>W</sub> of SU(2) (index <sub>123</sub>), because it has I<sub>W</sub> = 1:

- The fields of the physical charged bosons:  $W^{\pm} = (W_1 \mp iW_2) / \sqrt{2}$ ;
- For each doublet of fermions there is a 4-vector, which is at the same time a 3-vector in the I<sub>W</sub> space, which represents the weak current:

$$j_{\mu} \equiv (j_{\mu 1}, j_{\mu 2}, j_{\mu 3});$$

- The field  $W_\mu$  is coupled to  $j_\mu$  as (g  $W_\mu$   $j_\mu$ ) through the dimensionless coupling constant g.
- The charged currents are linear combinations of two current components  $j^{\pm} = (j_1 \pm j_2)$ .
- E.g., consider the doublet ( $v_{eL}$ ,  $e_L^-$ ); the corresponding charged currents are

$$j_{e\mu}^+ = \overline{\nu}_{eL} \gamma_{\mu} e_L^-; \qquad j_{e\mu}^- = \overline{e}_L^- \gamma_{\mu} \nu_{eL}.$$

**The field B**<sub> $\mu$ </sub> is a 4-vector in space-time and a scalar in isospin (I<sub>W</sub> = 0). It interacts with the neutral current of the leptons j<sub> $\mu$ </sub> (4-vector - isoscalar) through the coupling constant g'.

• The current generated by the hypercharge is twice the difference between the electric current  $j_{\mu}^{EM}$  and the neutral component of the NC :

$$Y_W = 2 (Q - I_{Wz}) \rightarrow j_{\mu}^Y = 2j_{\mu}^{EM} - 2j_{3\mu}.$$

- The first term is the electromagnetic current, which for charged fermions is  $j_{f\mu}^{\text{EM}} = \overline{f} \gamma_{\mu} f.$
- The chirality is not specified because the electro-magnetic interactions do not depend on it.

 $<sup>^{(*)}</sup>$  warning : here the  $\mu$  index refers to the spacetime dimensions, NOT to the  $\mu^\pm$  lepton.

# the e.w. theory: mixing angle $\theta_w$

Call **A** and **Z** respectively the physical fields that mediate the electromagnetic and neutral currents.

- They are two mutually orthogonal linear overlap of W<sub>3</sub> and B, which can be determined by requiring that the photon does not couple to the neutral particles, contrary to the Z.
- The transformation is given as a function of two couplings g and g', i.e. as a rotation of an angle  $\theta_w$ , the mixing angle of the weak interactions [a.k.a. the *Weinberg angle*]:

$$\begin{pmatrix} Z \\ A \end{pmatrix} = \frac{1}{\sqrt{g^2 + g^{1^2}}} \begin{pmatrix} g & -g' \\ g' & g \end{pmatrix} \begin{pmatrix} W_3 \\ B \end{pmatrix} =$$

$$= \begin{pmatrix} \cos \theta_w & -\sin \theta_w \\ \sin \theta_w & \cos \theta_w \end{pmatrix} \begin{pmatrix} W_3 \\ B \end{pmatrix};$$

$$\tan \theta_w = g'/g.$$

- The mixing angle is quite large,  $\theta_{\rm w} \approx 29^{\circ}$ .
- The interaction Lagrangian, being symmetric under the gauge group, is an isoscalar:

$$\mathcal{L} = g \left( j_{\mu 1} W_{\mu 1} + j_{\mu 2} W_{\mu 2} + j_{\mu 3} W_{\mu 3} \right) +$$

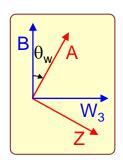

$$+ \frac{1}{2} g' j_{\mu}^{\gamma} B_{\mu'}$$

which can also be written as:

$$\mathcal{L} = g/\sqrt{2} (j_{\mu}^{-}W_{\mu}^{+} + j_{\mu}^{+}W_{\mu}^{-}) +$$

$$+ j_{\mu}^{3} (gW_{\mu 3} + g'B_{\mu}) +$$

$$+ g' j_{\mu}^{EM}B_{\mu}.$$

# the e.w. theory: interactions

 Then, introducing the neutral physical fields:

$$\begin{split} \mathscr{L} &= \frac{g}{\sqrt{2}} \Big( j_{\mu}^{-} W_{\mu}^{+} + j_{\mu}^{+} W_{\mu}^{-} \Big) + \\ &+ \frac{g}{\cos \theta_{w}} \Big( j_{\mu 3} - \sin \theta_{w} j_{\mu}^{EM} \Big) Z_{\mu} + \\ &+ g \sin \theta_{w} j_{\mu}^{EM} A_{\mu}. \end{split}$$

• The equation contains three terms :

**CC**: the charged current interactions;

**NC**: the neutral current interactions;

**EM**: the electromagnetic interactions.

• The constant which multiplies the last term has to be proportional to the electrical charge, to ensure that the photon is NOT coupled to neutral particles ( $\hbar$  = c = 1):

$$g sin\theta_w = q_e = \sqrt{4\pi\alpha}$$
.

- All the interactions, mediated by the four vector bosons, are expressed in terms of two constants, the electric charge  ${\bf q}$  and the weak angle  ${\bf \theta}_{\bf w}$ .
- However, the model does not predict the values of the two fundamental constants, which must be determined experimentally.
- The numerical relations between the fundamental constants, obtained from low-energy value of  $\alpha$  ( $\approx$  1/137) and the best measurement of  $\theta_w$ ) ( $\sin^2\!\theta_w \approx 0.232$ ), are :

$$\frac{1}{\alpha} = \frac{4\pi}{g^2} + \frac{4\pi}{g^{'2}}; \quad \frac{4\pi}{g^2} = 31.8; \quad \frac{4\pi}{g^{'2}} = 105.2.$$

 The second term in the equation gives the coupling between the Z and the fermions.

×

# the e.w. theory: summary of formulæ

 The Z coupling is "universal": it only depends on the electric charge and weak isospin:

$$\begin{split} g_z &\equiv \frac{g}{\cos\theta_w} \Big[ I_{w_z} - Q \sin^2\!\theta_w \Big] = \\ &= \frac{\sqrt{4\pi\alpha}}{\sin\theta_w \cos\theta_w} \Big[ I_{w_z} - Q \sin^2\!\theta_w \Big]. \end{split}$$

warning: these formulæ (and all those of this chapter) are simple and elegant, but only valid at 1<sup>st</sup> order; the devil lies in the details (= higher order corrections).

#### Summary:

$$m_w^2 = \frac{\sqrt{2}g^2}{8G_F} = \frac{\pi\alpha}{\sqrt{2}G_F \sin^2\theta_w} = \left(\frac{37.3}{\sin\theta_w} \text{ GeV}\right)^2$$

$$g\sin\theta_{\rm w} = q_{\rm e} = \sqrt{4\pi\alpha}$$

$$G_F = \frac{\sqrt{2}g^2}{8m_w^2}$$

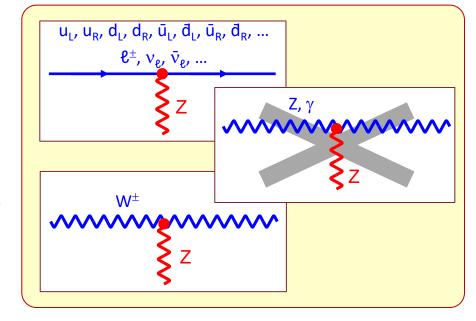

$$\tan \theta_{\rm w} = \frac{\rm g'}{\rm g}$$

$$\left|\frac{\pi}{2} + \frac{4\pi}{2}\right|$$
  $m_w = m_z \cos \theta_w$ 

# the e.w. theory: NC

- The Neutral Currents (NC) have important differences compared to CC.
- NO FCNC, i.e. fermions are only coupled with themselves (e.g.  $e^- \leftrightarrow e^-$ ,  $u_{red} \leftrightarrow u_{red}$ , NOT  $u_{red} \leftrightarrow u_{blue}$ , NOT  $u \leftrightarrow c$ , etc).
- They do not have the simple coupling  $[\gamma_{\mu}(1-\gamma_5)$ , i.e. "V A"], but are a mixture of both left and right couplings.
- The currents of the 1<sup>st</sup> family (the other families are similar) are:

$$\begin{split} &J(\nu) = \frac{1}{2}g_L^{\nu_e}\overline{\nu}_e\gamma_\mu \Big(1-\gamma_5\Big)\nu_e = g_L^{\nu_e}\overline{\nu}_eL\gamma_\mu\nu_{eL};\\ &J(e) = \frac{1}{2}g_L^e\overline{e}\gamma_\mu \Big(1-\gamma_5\Big)e + \frac{1}{2}g_R^e\overline{e}\gamma_\mu \Big(1+\gamma_5\Big)e = g_L^e\overline{e}_L\gamma_\mu e_L + g_R^e\overline{e}_R\gamma_\mu e_R;\\ &J(u) = \frac{1}{2}g_L^u\overline{u}\gamma_\mu \Big(1-\gamma_5\Big)u + \frac{1}{2}g_R^u\overline{u}\gamma_\mu \Big(1+\gamma_5\Big)u = g_L^u\overline{u}_L\gamma_\mu u_L + g_R^u\overline{u}_R\gamma_\mu u_R;\\ &J(d) = \frac{1}{2}g_L^d\overline{d}\gamma_\mu \Big(1-\gamma_5\Big)d + \frac{1}{2}g_R^d\overline{d}\gamma_\mu \Big(1+\gamma_5\Big)d = g_L^d\overline{d}_L\gamma_\mu d_L + g_R^d\overline{d}_R\gamma_\mu d_R. \end{split}$$

i.e. 7 parameters [given in § 7]

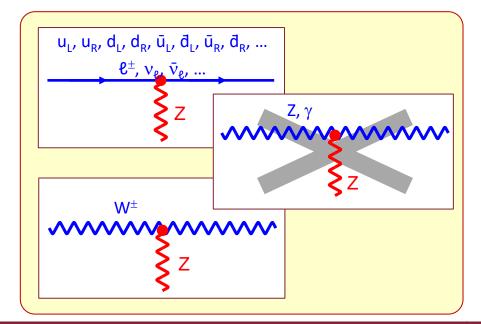

# the e.w. theory: NC couplings

- In the SM the 7 couplings are equal for the 3 families and functions of only two parameters ( $\alpha_{em}$  and  $\theta_{w}$ ).
- The Z couples with quarks/leptons:
  - > charged fermions, both L and R;
  - > v's and  $\bar{v}$ 's, even if they have no charge, because they have  $I_{Wz} \neq 0$ ;
  - $\gt W^{\pm}$ .
- The Z is NOT coupled (<u>in lowest order</u>) to particles with both Q = 0 and  $I_{Wz} = 0$ , i.e. the  $\gamma$  and the Z itself (and the gluons).
- In NC processes, the unification of the weak and electromagnetic interactions is particularly evident.
- The following tests have been performed [those with ">" will be discussed in these lectures]:

- parity violation in atoms (scale = eV);
- $\triangleright$  DIS  $v_{\mu}$  on electron (scale = MeV);
- scattering of polarized electrons on D<sub>2</sub> (GeV);
- > asymmetries in  $e^+e^- \rightarrow \mu^+\mu^-$  (from 10 GeV to 200 GeV );
- > DIS  $v_{\mu}$  and  $\bar{v}_{\mu}$  on nuclei (several GeV);
- > the measurement of Z parameters themselves.

\*

### electroweak results: theory ↔ exp

- All the couplings can be expressed in terms of the values of g and g' (usually  $\alpha$  and  $\theta_w$ ).
- The experiments measure observables (cross sections, decay rates, ...) and compare calculated 
   → measured quantities.
- The calculation is based on a "perturbative series", up to a certain order: lowest order (= "tree level"), subsequent orders (= "radiative corrections").
- The table shows an incomplete set of e.w. results since '70s: <u>hundreds</u> of measurements, <u>no inconsistency</u> found, <u>no disagreement</u>.
- In the following chapters a small part of the measurements will be examined, in the context of their experimental environment (e.g. LEP).
- The overall picture is impressive.

#### **Score**

- ✓ CC processes at low energy : well described by Fermi theory.
- ✓ NC processes : direct test of unification.
- ✓ Gauge boson ( $W^{\pm}$ , Z) existence.
- ✓ Gauge boson (W $^{\pm}$ , Z,  $\gamma$ ) coupling.
- ✓ Fermion mass generation (Higgs boson existence).
- ? Higgs boson couplings (\*).
- ✓ Quark mixing and CP violation (\*).
- ? Neutrino masses.
- ? Neutrino mixing.

<sup>(\*)</sup> Looks OK, with some possibility of surprises.

### QCD

- The <u>color</u> quantum number had been introduced [see § 1] to explain the <u>presence of the Δ<sup>++</sup></u>, in apparent violation of the Pauli principle;
- color is also necessary to explain the value of  $\mathbf{R}$  [= $\sigma_{\text{hadrons}}/\sigma_{\mu+\mu-}$ ] in e<sup>+</sup>e<sup>-</sup> interactions, which shows an excess, exactly of a factor 3 [see § 3];
- in a similar way, it is necessary to explain the decay rate  $\pi^0 \rightarrow \gamma\gamma$  [next slide].
- all these observations have convinced the physicists that the color is at the core of the dynamics of the hadrons.

- the theory must also explain <u>confinement</u>
   (= no free quarks) and <u>asymptotic</u>
   <u>freedom</u> (= scaling at high Q<sup>2</sup>).
- the modern **QCD** is a gauge theory based on the symmetry SU(3)<sub>color</sub>, mathematically equivalent to SU(3)<sub>flavor</sub>, but based on a completely different dynamics.
- the carriers of the force are 8 colored massless vector (= spin 1) bosons, called gluons ["glue" as an example of a strong force with short range].
- compared to QED, the differences are in the behavior of the fields:

	"matter" = fermions			"fields" = bosons				
	name	spin	"charge"	name	spin	"charge"	mass	self- coupling
QED	leptons+quarks	1/2	yes	γ	1	no	no	no
QCD	quarks	1/2	yes	8 gluons	1	<u>yes</u>	no	<u>yes</u>

### QCD: $\pi^0$ decay

[the  $\pi^0$  decay is an <u>e.m. process</u>, NOT a strong one; we discuss it here because it critically depends on the number of colors, i.e. on a QCD parameter.]

- An independent test of the color charge of the quarks comes from a completely different measurement, the  $\pi^0$  decay;
- compute the decay amplitude, by introducing an (a-priori unknown) arbitrary normalization factor "N<sub>c</sub>":

$$\left\langle \gamma \gamma \left| \mathbb{H}_{em} \right| \pi^{0} \right\rangle = \left\langle \gamma \gamma \left| \mathbb{H}_{em} \left| \frac{\left( u \overline{u} - d \overline{d} \right)}{\sqrt{2}} \right\rangle \right.$$

$$\propto f_{\pi} \frac{N_{c}}{\sqrt{2}} \left( \frac{4}{9} e^{2} - \frac{1}{9} e^{2} \right);$$

where  $f_{\pi}$  is the decay constant of the  $\pi^{0}$ , which is related to the wave-function overlap of the quark and antiquark;

• the full computation gives<sup>(\*)</sup>:

$$\Gamma\left(\pi^{0} \to \gamma\gamma\right)\Big|_{\text{theo.}} = \left(\frac{\mathsf{q}_{\mathsf{u}}^{2} - \mathsf{q}_{\mathsf{d}}^{2}}{\mathsf{e}^{2}}\right)^{2} \frac{\mathsf{N}_{\mathsf{c}}^{2}\alpha^{2}\mathsf{m}_{\pi}^{3}}{32\pi^{3}\mathsf{f}_{\pi}^{2}} =$$

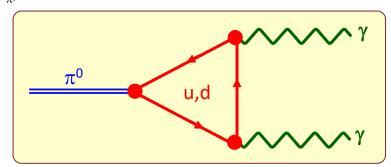

$$= 7.64 \left(\frac{\mathsf{N}_{\mathsf{c}}}{3}\right)^{2} \; \mathsf{eV};$$

$$\Gamma\left(\pi^{0} \to \gamma\gamma\right)\Big|_{\mathsf{exp.}} = (7.84 \pm 0.6) \; \mathsf{eV};$$

$$\to \mathsf{N}_{\mathsf{c}} = 2.96 \pm 0.11,$$

not compatible with  $N_c=1$ , but with the QCD prediction  $N_c=3$ .

<sup>(\*)</sup> warning : " $32\pi^3 f_{\pi}^2$ " depends on the definition of  $f_{\pi}$ ; also 16 or 64 in the literature.

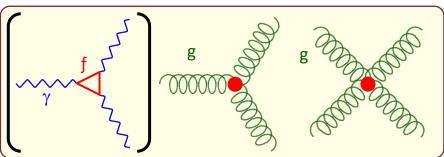

\*

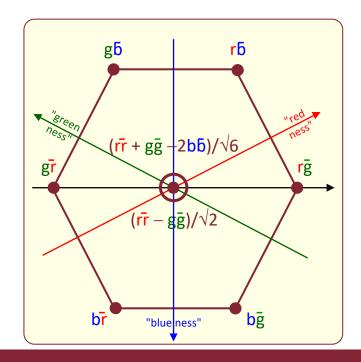

### QCD: color

The **color** is a charge, equivalent to the electric charge:

- it is exactly conserved in the processes;
- it obeys the "video-display" rgb rules (e.g. red + green = vellow, so vellow = anti-blue);
- a gluon carries two colors (which is equivalent to an anti-color, see above);
- gluons are colored, therefore self-coupled; the vertex with three bosons is allowed in QCD, while in QED it happens only on higher orders (with a triangle of fermions); also 4-gluons verteces are allowed;

- the number of gluons (8) comes from the number of generators of SU(3) (Gell-Mann matrices [see § 1]);
- similarly, it comes from the independent combinations of two rgb ( $r\bar{r}$ ,  $g\bar{g}$ ,  $b\bar{b}$ ,  $r\bar{b}$ ,  $r\bar{g}$ ,  $g\bar{b}$ ,  $g\bar{r}$ ,  $b\bar{r}$ ,  $b\bar{g}$ ), after removing the singlet combination [( $r\bar{r} + g\bar{g} + b\bar{b}$ ) /  $\sqrt{3}$ ];
- the gluon octet is similar to the qq̄ one :

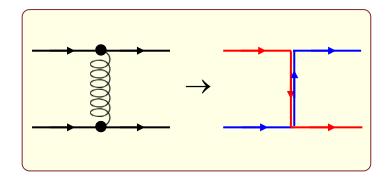

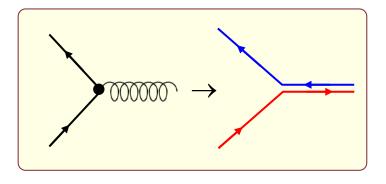

# QCD: gluon color

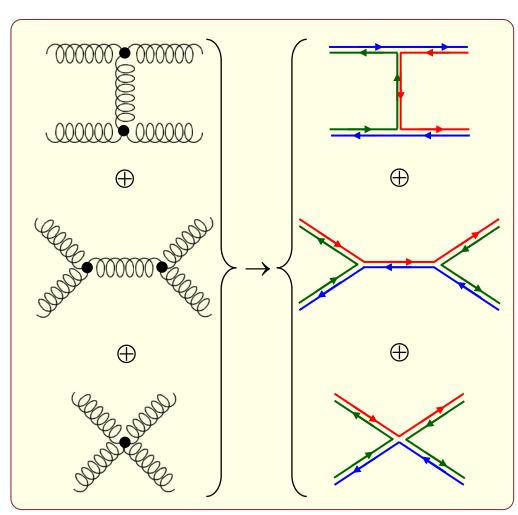

Examples of quark-gluon diagrams with emphasis on color conservation :

- in this page, color is "QCD-color";
- only one shown of the many color permutations;

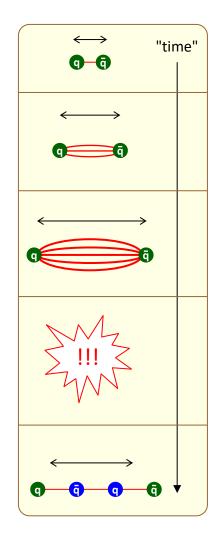

### **QCD**: confinement

- The color does NOT manifest <u>directly</u> in an <u>observable</u> <u>property</u> of the particles (something like a "red" particle has never been observed).
- The standard explanation of this fact requires that only "white" ("color singlets") states be physically existent.
- The consequence is that quarks and gluons themselves cannot be observed as free states (<u>confinement</u>); they exist only inside "molecules" (= hadrons)
- The mathematical formalism of QCD gives an account for that.
- Some naïve classical models, with similarity to springs and magnetism (the "broken magnet") are often quoted.
- An important consequence is that partons (quarks and gluons), created in e<sup>+</sup>e<sup>-</sup> or hadronic scattering, must undergo a complicated mechanism which finally produces only <u>color singlets</u> (hadrons) in a spray of particles (<u>jets</u>).

### QCD: asymptotic freedom

- From the study of the DIS, we have learned that at high Q<sup>2</sup>, the projectile "sees" smaller scales inside the nucleon.
- At small distances the force between quarks and gluons is apparently smaller and smaller: the quarks behave as free objects; the scattering onto free quarks is the origin of the <u>Bjorken scaling</u> [§ 2].
- This effect is called <u>asymptotic freedom</u> [Gross, Politzer, Wilczek – Nobel Prize 2004].
- With <u>increasing distance</u> among the quarks, the intensity of the strong force increases, keeping the quarks "confined" in the nucleon.
- As we have already mentioned, at some distance the available energy becomes sufficient to create a new <u>quark-antiquark</u>

- pair, eventually leading to the production of new hadron(s), but <u>PREVENTING</u> the emission of quarks as free particles.
- Summary: among quarks there exists a "color" field. The gluons that mediate this force act as additional sources of the color field ("gluons are non-abelian"). The gluon-gluon interaction "pulls" the lines of force of the color in a narrow tube, a sort of a "string", similar to a spring, whose tension ("= potential energy") increases with length.

### **QCD**: hadrons

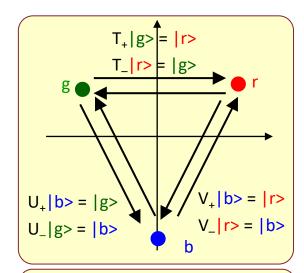

#### remember §1, "color"

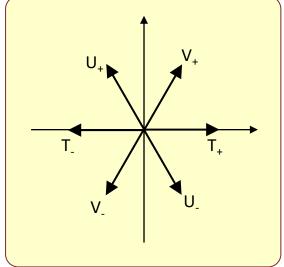

The particles of the theory are built from the SU(3) rules.

Technically, introduce the ladder operators  $T_{\pm}$ ,  $U_{\pm}$ ,  $V_{\pm}$  [§1 + the QCD dynamics]:

- mesons are color singlets [a qq̄ pair with symmetric wave function:  $(r\bar{r} + g\bar{g} + b\bar{b}) / \sqrt{3}$ ];
- <u>baryons</u> are also color singlets [qqq with antisymmetric w.f.:  $(rgb + gbr + brg grb bgr rbg) / \sqrt{6}$ ;
- [mesons are their own anti-particles]
- [anti-baryons are qqq states with the same rules]
- puzzling: there are also other possible color singlets:
   qqqq, qqqqq [next slide], or glue-glue bound states...
- <u>no (QCD-based) rule</u> forbids their existence; in the past there have been (well founded?) claims of discovery (tetraquarks, pentaquarks, glueballs, ...).

here "rgb" are quarks with the appropriate flavor.

 $\bigstar$ 

# $QCD:SU(3)_{c}$

С	B	I <sub>Cz</sub>	Y <sub>C</sub>	С	В	I <sub>Cz</sub>	Y <sub>C</sub>
r	+1// <sub>3</sub>	+½	+1// <sub>3</sub>	ī	<b>−⅓</b>	-1/2	<b>−⅓</b>
g	+1// <sub>3</sub>	-1/2	+1// <sub>3</sub>	īg	<b>−⅓</b>	+½	-1/3
b	+1// <sub>3</sub>	0	-2/3	Б	-1/3	0	+2/3

- mathematically identical to SU(3)<sub>flavor</sub> (<u>see</u>);
- define a "color isospin" (I<sub>C</sub>, I<sub>Cz</sub>) and a "color hypercharge" (Y<sub>C</sub>);
- rgb just names, no connection with ordinary "colors";
- for baryons,  $\psi_{color}$ :
  - >  $\mathbf{B} = 1 \Rightarrow 3$ -quarks (or 3 antiquarks);
  - normalized;
  - > overall color = 0;
  - anti-symmetric (Pauli principle);

$$\psi_{\text{color}}^{\text{baryons}} = \frac{1}{\sqrt{6}} \begin{pmatrix} \textbf{r}_{1}\textbf{g}_{2}\textbf{b}_{3} + \textbf{g}_{1}\textbf{b}_{2}\textbf{r}_{3} + \textbf{b}_{1}\textbf{r}_{2}\textbf{g}_{3} + \\ -\textbf{r}_{1}\textbf{b}_{2}\textbf{g}_{3} - \textbf{b}_{1}\textbf{g}_{2}\textbf{r}_{3} - \textbf{g}_{1}\textbf{r}_{2}\textbf{b}_{3} \end{pmatrix};$$

The most general quark combination is:

$$\psi_{color} = r^{\alpha} g^{\beta} b^{\gamma} \overline{r}^{\overline{\alpha}} \overline{g}^{\overline{\beta}} \overline{b}^{\overline{\gamma}}; \qquad [\alpha, \beta, ... \text{ integer}]$$

define (whithout loss of generality):

$$\mathbf{m} \equiv \alpha + \beta + \gamma \ge \mathbf{n} \equiv \overline{\alpha} + \overline{\beta} + \overline{\gamma};$$

$$I_{c_2} = (\alpha - \overline{\alpha})/2 - (\beta - \overline{\beta})/2 = 0;$$

$$Y_C = (\alpha - \overline{\alpha})/3 + (\beta - \overline{\beta})/3 - 2(\gamma - \overline{\gamma})/3 = 0;$$

$$\Rightarrow$$
  $(\alpha - \overline{\alpha}) = (\beta - \overline{\beta}) = (\gamma - \overline{\gamma}) \equiv p;$ 

$$\Rightarrow \alpha + \beta + \gamma - \overline{\alpha} - \overline{\beta} - \overline{\gamma} = m - n = 3p; p \ge 0;$$

$$\Rightarrow \psi_{color} \equiv q^m \overline{q}^n = q^{3p+n} \overline{q}^n = (qqq)^p (q\overline{q})^n$$
.

#### The simplest cases are:

- p = 1, n = 0  $\rightarrow$  baryons qqq (+ anti-);
- p = 0, n = 1  $\rightarrow$  mesons q $\overline{q}$ ;
- many other possibilities NOT forbidden,

e.g. (p=n=1; p=0,n=2) 
$$\rightarrow$$
 (qqq q $\overline{q}$ ; q $\overline{q}$ q $\overline{q}$ );

• searches (and claims...).

# QCD: multiquarks? glueballs?

#### Modern remark on tetra- and penta-quarks

M.Karliner et al, Annu. Rev. Nucl. Part. Sci. 68:17-44 (2018) [emphasis mine]:

Why do we see certain types of elementary particles and not others? This question was posed more than 50 years ago in the context of the quark model. Gell-Mann and Zweig proposed that the known mesons were  $q\bar{q}$  and baryons qqq, with the quarks known at the time, u (up), d (down), and s (strange), having charges of  $\frac{2}{3}$ ,  $-\frac{1}{3}$ , and  $-\frac{1}{3}$ , respectively. Mesons and baryons would then have integral charges.

Mesons such as qqqq and baryons such as qqqqq would also have integral charges. Why weren't they seen? *They have now been seen*, but only with additional heavy quarks and under conditions that tell us a lot about the strong interactions and how they manifest themselves.

*(...)* 

A look back at the experimental developments in hadron spectroscopy in the new millennium

shows that heavy quarks have done it again! After converting us into firm believers in the quark model in the 1970s, heavy quark systems have taught us a new lesson: Not all hadronic states are minimal quark combinations. In addition to  $q\bar{q}$  mesons, four-quark  $qq\bar{q}\bar{q}$  configurations become important, especially near and above the  $q\bar{q}+q\bar{q}$  meson thresholds. Similarly, not all baryons are qqq states;  $qqqQ\bar{Q}$  configurations also play a role.

Theoretical disputes continue as to whether the observed multiquark configurations are tightly bound tetra- and penta-quarks or loosely bound meson-meson and baryon-meson molecules. In our opinion, the case for the latter is stronger. It is also beyond dispute that baryon-baryon molecules exist and have been known for a long time as nuclei.

(...)

### **Strong interactions: the QCD game**

#### Process (qqg) (qqg) $\rightarrow$ (qqg) (qqg):

- picture only valid <u>at high Q</u><sup>2</sup>: at low Q<sup>2</sup> hadrons scatter coherently (see § 2-8),
   → rest of discussion assumes high Q<sup>2</sup>;
- 8 cases, according to (qqg) [next slide];
- impossible to disentangle on an event-byevent basis (in QED e<sup>+</sup>e<sup>+</sup> and e<sup>+</sup>e<sup>-</sup> not in the same accelerator, while in QCD qq and qq̄ possible, because of valence/sea) [an advantage, but a difficult one];
- therefore all processes mixed together, difficult (≈ impossible) to disentangle on an event-by-event basis: only statistical mixtures measurable;
- weights of stat. mixture are couplings at parton level (get from theory) \* PDF (parametrize/evolve) [a difficult game];

- in hadronic initial states (h.i.s.) the energy at parton level (\$\hat{s}\$) is different from energy at hadron level (s); same for \$\hat{t}\$ and \$\hat{u}\$ ↔ t and u [next slide uses stu, but means \$\hat{t}\$û];
- in h.i.s. s from beam energy, but \$ difficult
   [§ 8] and different for each event;
- jets, not single partons in final state: in general (q ↔ q̄ ↔ g) not distinguishable, single quarks (e.g. b ↔ u d) difficult;
- t-channels much more abundant than ŝ-channels; gluon channels more abundant than quark-: a disgrace for the search of W<sup>±</sup>, Z, H, which mainly come from q-q̄ processes in the ŝ channel.

<u>Conclusion</u>: a rich and difficult game, which requires a lot of events, strong computing power, intelligent analysis.

the strong interactions in QCD: •  $q' : q' \neq q$ .

----  $\gamma_{QED}$  or  $g_{QCD}$ .

# Strong interactions : the coupling $\alpha_s$

A semi-classical approach for the QCD potential from experimental data :

• for small distances (r  $\rightarrow$  0), Coulomb shape, with a stronger coupling  $\alpha_s$  (instead of  $\alpha_{em}$ ):

$$V(\text{small r}) = -4\alpha_s / (3 \text{ r})$$

 at high distances (r → ∞), a linearly increasing function, responsible for confinement:

$$V(large r) = k r$$

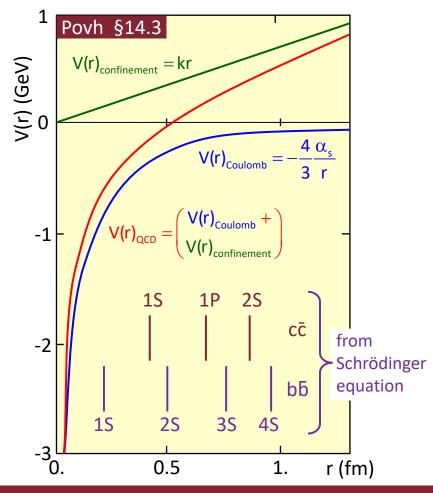

• all together (see fig):

$$V(r) = -4\alpha_s / (3r) + k r$$

- parameters  $\alpha_s$  and k adjusted to fit data :  $\alpha_s \approx 0.15 \div 0.25$ , k  $\approx 1$  GeV fm<sup>-1</sup>;
- then (numerically) solve the Schrödinger equation and derive (e.g.) the properties of bound states;

see also [MS, 6.4.3] for  $V(r) = A \ln (r/B)$ .

- approximation supposed to work better in non-relativistic case, V << m;</li>
- (fair) agreement with reality, especially in the heavy quark sector.

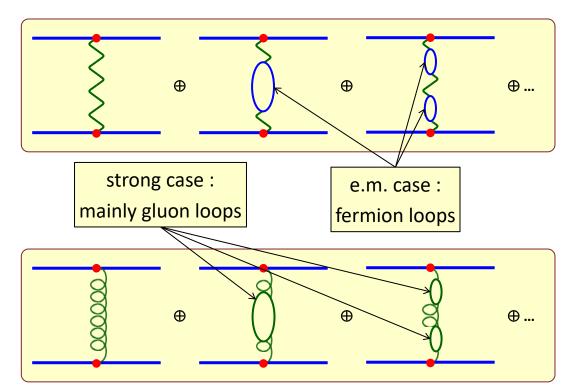

# **Strong interactions** : $\alpha_s = \alpha_s(Q^2)$

More effective approach for scattering processes :  $\underline{reabsorb}$   $\underline{higher\ orders}$  into an effective  $\alpha_s$  :

- $\rightarrow$  loops increases for higher Q<sup>2</sup>;
- $\rightarrow$  evolution of the coupling  $\alpha_s$  from its low-Q<sup>2</sup> value, with standard Feynman techniques;

Important difference  $\alpha_{\text{\tiny S}} \! \leftrightarrow \! \alpha_{\text{\tiny em}}$  :

- higher order loops in  $\alpha_{\rm em}$  only due to fermions  $\rightarrow$  <u>increase</u> of  $\alpha_{\rm em}$  as a function of Q<sup>2</sup>;
- instead, since the gluons are selfcoupled, loops in  $\alpha_s$  mainly due to bosons  $\rightarrow$  <u>decrease</u> of  $\alpha_s$  with Q<sup>2</sup>;
- the formulæ show the "running" of  $\alpha_{em}$  and  $\alpha_{s}$  with Q<sup>2</sup> :
- (confinement and asymptotic freedom automatically produced).

$$\alpha_{em}\left(Q^{2}\right) = \alpha_{em}\left(Q_{0}^{2}\right) / \left[1 - \frac{\alpha_{em}\left(Q_{0}^{2}\right)}{3\pi} ln\left(\frac{Q^{2}}{Q_{0}^{2}}\right)\right];$$

$$\alpha_{s}\left(Q^{2}\right) = \alpha_{s}\left(Q_{0}^{2}\right) / \left[1 + \alpha_{s}\left(Q_{0}^{2}\right) \frac{11N_{c} - 2N_{f}}{12\pi} ln\left(\frac{Q^{2}}{Q_{0}^{2}}\right)\right].$$

\*

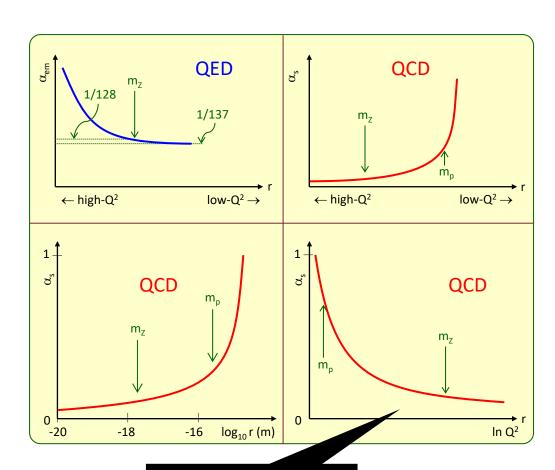

# Strong interactions : $\alpha_s \leftrightarrow \alpha_{e.m.}$

$$\alpha_s\left(Q^2\right) = \alpha_s\left(Q_0^2\right) / \left[1 + \alpha_s\left(Q_0^2\right) \frac{11N_c - 2N_f}{12\pi} ln\left(\frac{Q^2}{Q_0^2}\right)\right]; \quad N_c = 3; \quad N_f = 3 \rightarrow 4 \rightarrow 5 \rightarrow 6$$

The effective value of  $\alpha_s$  decreases as a function of Q<sup>2</sup>, thus explaining the nucleons (strongly bound partons) and the DIS (quasi-free partons).

Some care for the coefficients:

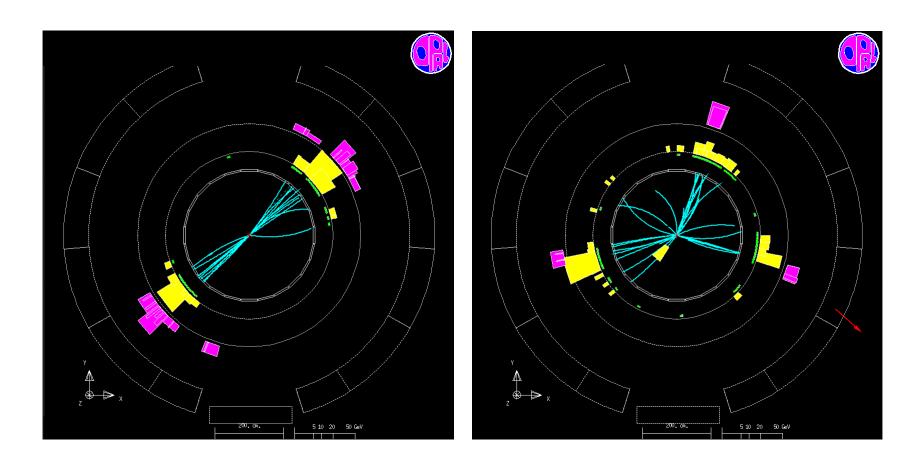

- "N<sub>c</sub>" = number of colors = 3;
- "N<sub>f</sub>" = number of flavors = 6;
- but N<sub>f</sub> = N<sub>f</sub>(Q<sup>2</sup>), i.e. the number of flavors which participate in the interactions at a given Q<sup>2</sup>;
- to be simple (but not entirely correct), at a given value of  $Q^2$ , only flavors with  $(2m_f)^2 < Q^2$  enter in the computation of  $\alpha_s$ .

for the exp. data, see later

\*

# Hadrons in the final state

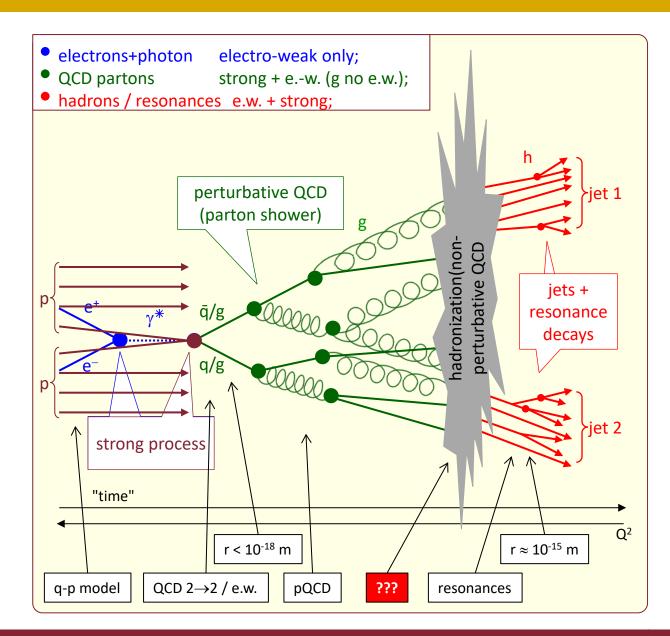

A two-jet and a three-jet event in OPAL.

#### Hadrons in the final state

Three phases after elementary process :

- parton shower:
   perturbative cascade of
   (q q
   g); notice the gluon
   self-coupling (non abelian);
- hadronization: low-Q<sup>2</sup>
   parton processes, <u>no</u>
   well-funded calculation;
- hadrons: decays of resonances and emergence of jets.

NB Lot of work in parameterizations, fitting, algorithms, speculations ...

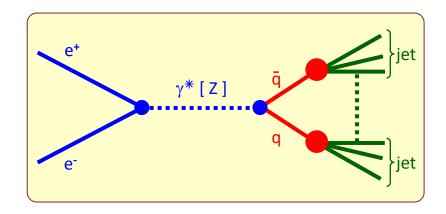

#### Hadrons in the final state

The jets can be identified with the partons of the final state;

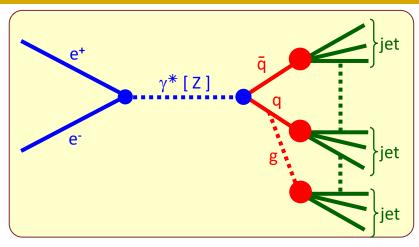

- problems :
  - to preserve the color, the two jets in the final state must "talk" each other (e.g. by exchange of gluons);
  - so it is impossible, strictly speaking, to assign in a given event a hadron (and hence a jet) to a "father" parton;
- however, as soon as Q<sup>2</sup> > (few GeV)<sup>2</sup>, the majority of the events presents two (rarely three) well identified jets, with essentially no ambiguity;
- from the experimental point of view, the situation is relatively simple:
  - ightharpoonup (in practice all) the events e<sup>+</sup>e<sup>-</sup> → hadrons for  $\sqrt{s}$  ≥ (few GeV) [SPEAR 1975] have two collimated jets of particles, opposite in  $\theta$  and  $\phi$ .

- the direction and momentum of the partons can be reconstructed from the vector sum of the 4-momenta of the hadrons (many subtleties, but the essence is simple);
- > it is also possible to measure the "fragmentation function" of the partons: f(z),  $z = E_{hadron} / E_{parton}$ ;
- more discussions in (§ SppS) and (§ LEP).

\*

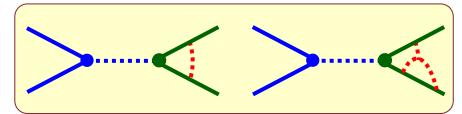

# 4/4 Hadrons in the final state: three-jet events

- Sometimes, a parton emits a gluon of bremsstrahlung, at an angle and with an energy such as to produce a third jet, well separated from the other two;
- usual litany : "the fraction of three-jet *events*  $\propto \alpha_s$ "; however :
  - > jets are "ill-defined" quantities : the number and 4-mom. of jets in an event depends on the analysis (the so-called jet-finding algorithm, *JFA*);
  - > the real meaning is that one has to compute (e.g. via montecarlo) the

yield of multi-jet events with a given JFA and a given value of  $\alpha_s$ ; then the comparison with the data, analysed with the same JFA, is a "meas." of  $\alpha_s$ (e.g. too few three-jets in MC wrt  $data \rightarrow \alpha_s^{MC} < \alpha_s^{true}$ );

- similarly, 4-jet, 5-jet, ...;
- with the previous caveats :
  - $\rightarrow$   $\sigma(2\text{-jet}) \propto \alpha_{\text{em}}^2$ ;  $\sigma(3\text{-jet}) \propto \alpha_{\text{em}}^2 \times \alpha_s$ ;
  - $\rightarrow$   $\sigma$ (3-jet) /  $\sigma$ (2-jet)  $\propto \alpha_s$ ;
  - $\triangleright \alpha_s$  can be measured by the ratio 3jet/2-jet [also many other ways];
- high value of  $\alpha_s$  [> 0.10]  $\rightarrow$  importance higher orders of the strong interactions, particularly true for multijets final states.

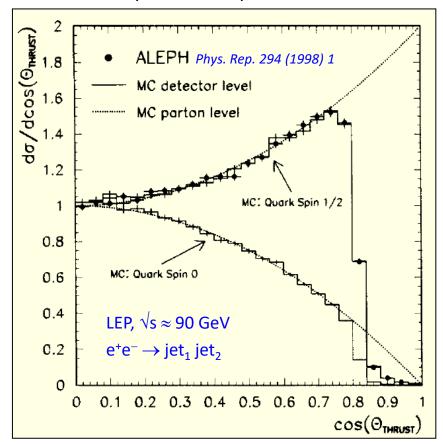

# QCD results: quark spin

- If quark-spin = lepton-spin =  $\frac{1}{2}$ , in  $e^+e^- \rightarrow jets^{(1)}$ ,  $d\sigma/d\Omega \propto d\sigma/d\Omega|_{\mu\mu} \propto (1+\cos^2\theta)$ ;
- however, the heavy quarks have a nonnegligible mass; their  $\theta$  dependence is :

$$\begin{split} \frac{d\sigma}{dcos\theta} &= \frac{\pi\alpha^2 e_q^2 N_c \beta_q^*}{2s} \Big( 2 - \beta_q^{*2} + \beta_q^{*2} \cos^2\theta \Big); \\ \beta_q^* &= \sqrt{1 - 4m_q^2/s}. \end{split}$$

- in reality, cannot distinguish jets from q and  $\bar{q} \rightarrow \exp$ . ambiguity  $(\theta \leftrightarrow 180^{\circ}-\theta)$ ,  $(\cos \theta \leftrightarrow -\cos \theta) \rightarrow \text{plot } |\cos \theta|$ ;
- the value of  $\theta$ , i.e. the quark direction, is given by the jet axis [see previous pages], usually identified with the "thrust" axis<sup>(2)</sup>;
- after all that, the comparison is possible, and <u>definitive</u> (e.g. ALEPH, 1998).

- (1) True for e.m. and not for NC; but at the Z pole, the qq asymmetry is small [see § LEP].
- (2) The thrust axis is the direction which minimizes the sum of the transverse momenta of the final state particles respect to it.

# QCD results: the gluon

Naïvely, the existence (both  $\sigma$  and  $d\sigma/d\Omega$ ) of three-jet events (apart from pedantic caveats on the JFA) is a convincing test of the existence of the gluon.

#### Other "proofs" include:

- the integral of the structure function F<sub>2</sub>(x), which demonstrates that ~50% of the nucleon momentum is NOT carried by charged partons;
- the overall agreement between QCD and measurements, e.g. for hadron colliders;

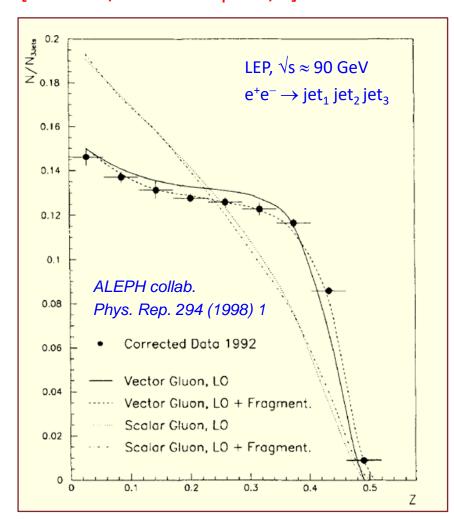

#### The spin of the gluon is measured:

- in e<sup>+</sup>e<sup>-</sup>, the third jet in three-jet events comes from gluon brem (theory : 75%);
- after ordering the jets according to energy, the variable

$$Z = 2 (E_2 - E_3) / \sqrt{3s}$$

is sensitive to the gluon spin value.

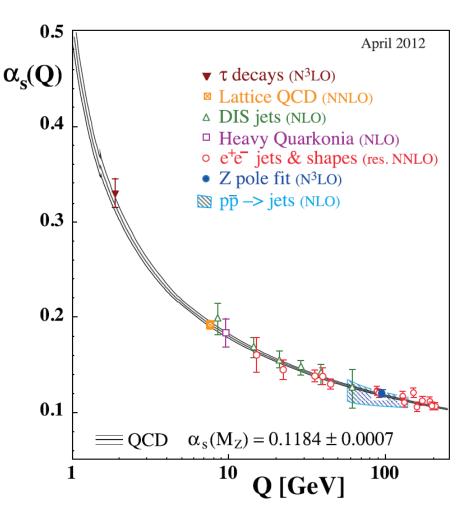

• OK !!! (e.g. ALEPH, notice the quality of the result, insensitive to fragmentation) ["vector"/"scalar" : spin 1/0].

# **QCD** results : the running of $\alpha_s$

- Actually the running of  $\alpha_s = \alpha_s(Q^2)$  has been shown, by measuring the strength of the coupling at different  $Q^2$ .
- The data of the figure show a variation of 100 in  $\sqrt{Q^2}$ , which ranges from  $\tau$  decay to jets at LHC energies.
- The measurements are compared with predictions, normalized to the value with smallest error, i.e. at Q<sup>2</sup> = m<sup>2</sup>(Z) [only the "running" can be computed in QCD, not the abs. value].
- The funny acronyms (N³LO, NNLO) refer to the computations: they are performed at a given order of Feynman diagrams: NLO = "next to leading order", NNLO = "next to next ..."...
- What does "Lattice QCD" mean?

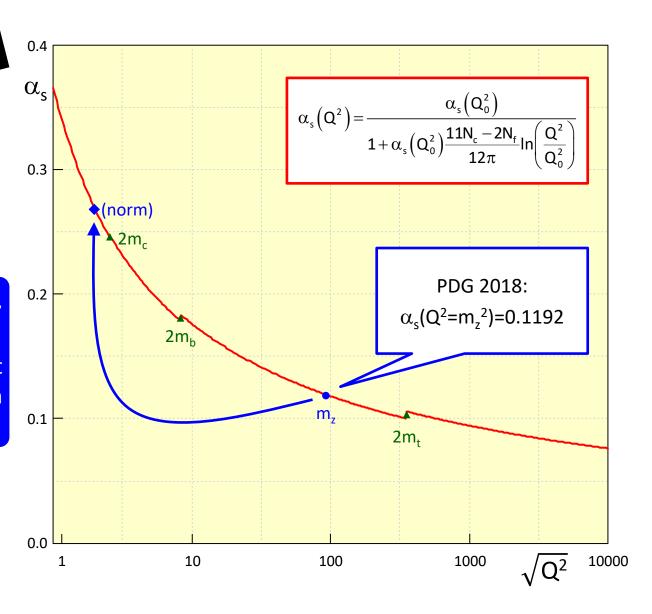

$$\alpha_{s}\left(Q^{2}\right) = \alpha_{s}\left(Q_{0}^{2}\right) / \left[1 + \alpha_{s}\left(Q_{0}^{2}\right) \frac{11N_{c} - 2N_{f}}{12\pi} ln\left(\frac{Q^{2}}{Q_{0}^{2}}\right)\right]$$

# **QCD** results : $\alpha_s = \alpha_s(Q^2)$

do NOT use for real computations, only useful as an exercise !!!

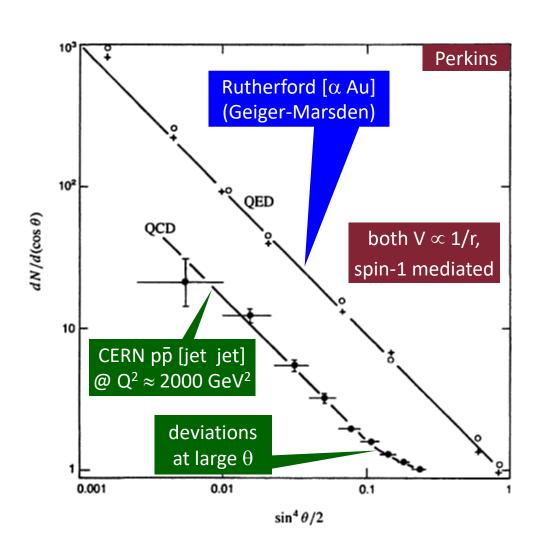

- A "home-made" plot, just for understanding;
- notice the steps at  $\sqrt{Q^2} = 2m_{q'}$  clearly an artefact of the approx.

# QCD results: angular distribution

Finally, an angular comparison is shown between QED and QCD:

- upper: Rutherford scattering (QED) in the famous Geiger-Marsden plot; the dependence
   ∞ 1 / sin<sup>4</sup>(θ/2) is evident;
- lower (arbitrary normalization): the same angular plot for  $\bar{p}p$  QCD jets at  $Q^2 \approx 2000 \text{ GeV}^2$ ;
- [notice that, one century ago, it was not customary to show errors on the plots; maybe in good ole time, they did not make errors].

#### "Grand unification bSM"?

Two curiosities on  $\alpha_s$ .

• Since  $\alpha_s > 0$  [any objection ?], it follows

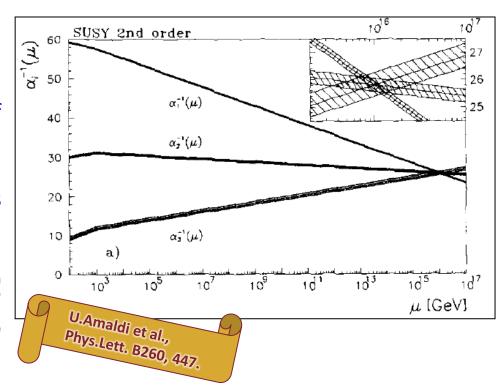

11 
$$N_c - 2 N_f > 0 \rightarrow$$
  
 $N_f < 11 N_c / 2 = 16.5;$ 

i.e. an upper limit on the number of flavors; after the LEP measurement of  $\Gamma_{\rm Z}$ , the argument has lost importance, even though there is a logical possibility (lots of heavy flavors with heavy neutrinos ...);

• Since  $\alpha_s = \alpha_s(Q^2)$  is decreasing, while  $\alpha_{em}$  is increasing, do they cross each other ? and, at this value of  $Q^2$ , what happens to gravity ?

It turns out that a model "beyond the Standard Model" (SUSY) predicts that, at  $\sqrt{Q^2} \approx 10^{15}$  GeV ( $\mu$  in the fig.), the three couplings [SU(3)<sub>c</sub> $\otimes$ SU(2)<sub>L</sub> $\otimes$ U(1)] have the

same value, therefore suggesting "grand unification".

Notice that in the SM the three constants all run, but badly miss each other (!!!).
