BICEP Array and Thermal Kinetic Inductance Detectors

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

Presentation outline

CMB Polarization

BICEP Array

Data analysis and latest results

The physics of TKIDs

System level design

Readout electronics

Deployment operations

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

CMB Polarization: modern cosmology in a nutshell

- 1) The universe is expanding. (Hubble, 1920s)

- 2) It was once hot and dense, like the inside of the Sun. (Alpher, Gamow, Herman, 1940s)

- 3) You can still see the glow! The Cosmic Microwave Background (Penzias & Wilson, 1964)

CMB Polarization: acoustic and gravitational oscillations

CMB Polarization: acoustic and gravitational oscillations

Temperature

Temperature fluctuations, Planck

Polarization

CMB Polarization: patterns

On a 2D plane

Density Wave

E-Mode Polarization Pattern

Temperature Pattern Seen by Electrons

Gravitational Wave

B-Mode Polarization Pattern

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

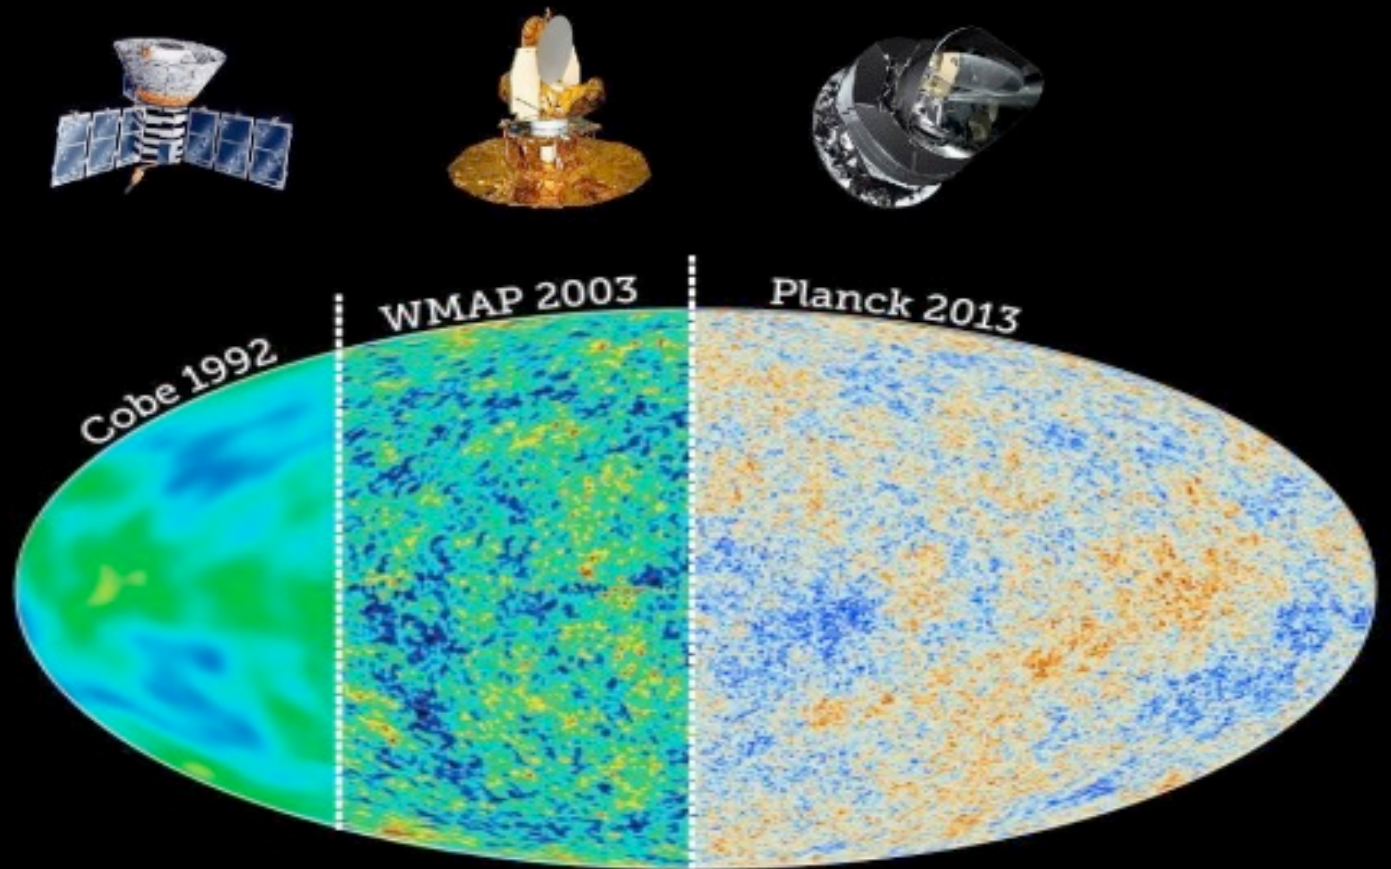

$$r = \frac{\Delta_h^2}{\Delta_{\mathcal{R}}^2} \left(\frac{V}{[2 \times 10^{16} \text{GeV}]^4} \right)$$

CMB Polarization

Precision measurements of the CMB temperature have provided a wealth of cosmological information consistent with the inflationary paradigm.

However, any imprint of the inflationary gravitational waves have so far eluded detection in the CMB.

BICEP Array: target and location

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

BICEP array: the collaboration

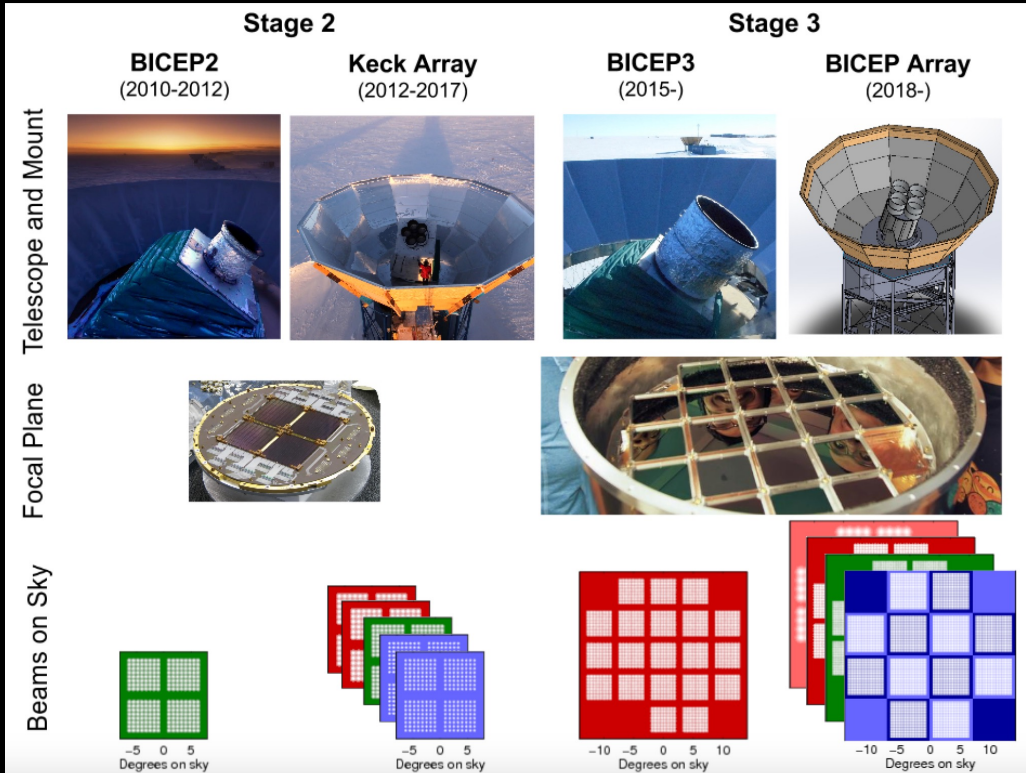

UNIVERSITY OF
TORONTO

BICEP Array: the BICEP program

BICEP Array

Four sub-millimeter wave telescope synchronously scanning a patch of sky with angular degree resolution

All science data have been collected using TES (transition edge sensors) technology

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

BICEP Array: the BICEP Array mount

Keck style,
Aperture: 26.4cm

BICEP3 style,
Aperture: 55cm

BICEP array: frequency selection

The dry South Pole atmosphere provides excellent observing conditions most of the year.

The approx. 30% fractional bandpasses fit within atmospheric transmission windows straddled by oxygen and water lines.

The detector passbands are defined by a filter printed directly onto the focal plane wafers

BICEP array: the BICEP/Keck telescope

Telescope as compact as possible while still having the angular resolution to observe degree-scale features.

On-axis, refractive optics allow the entire telescope to rotate around boresight for polarization modulation.

Pulse tube cooler cools the optical elements to 4.2 K.

A 3-stage helium sorption refrigerator further cools the detectors to 0.27 K.

BICEP array: focal plane and TES technology

1) Focal plane

2) A single tile

3) A single pixel with antenna

Frequency	30/40 GHz	95 GHz	150 GHz	220/270 GHz
# Detectors	192/300	3456	7776	13824/16224
# Det/Tile	32/50	288	648	1152/1352 !
Beam FWHM (arcmin)	76/57	24	15	10/8.5

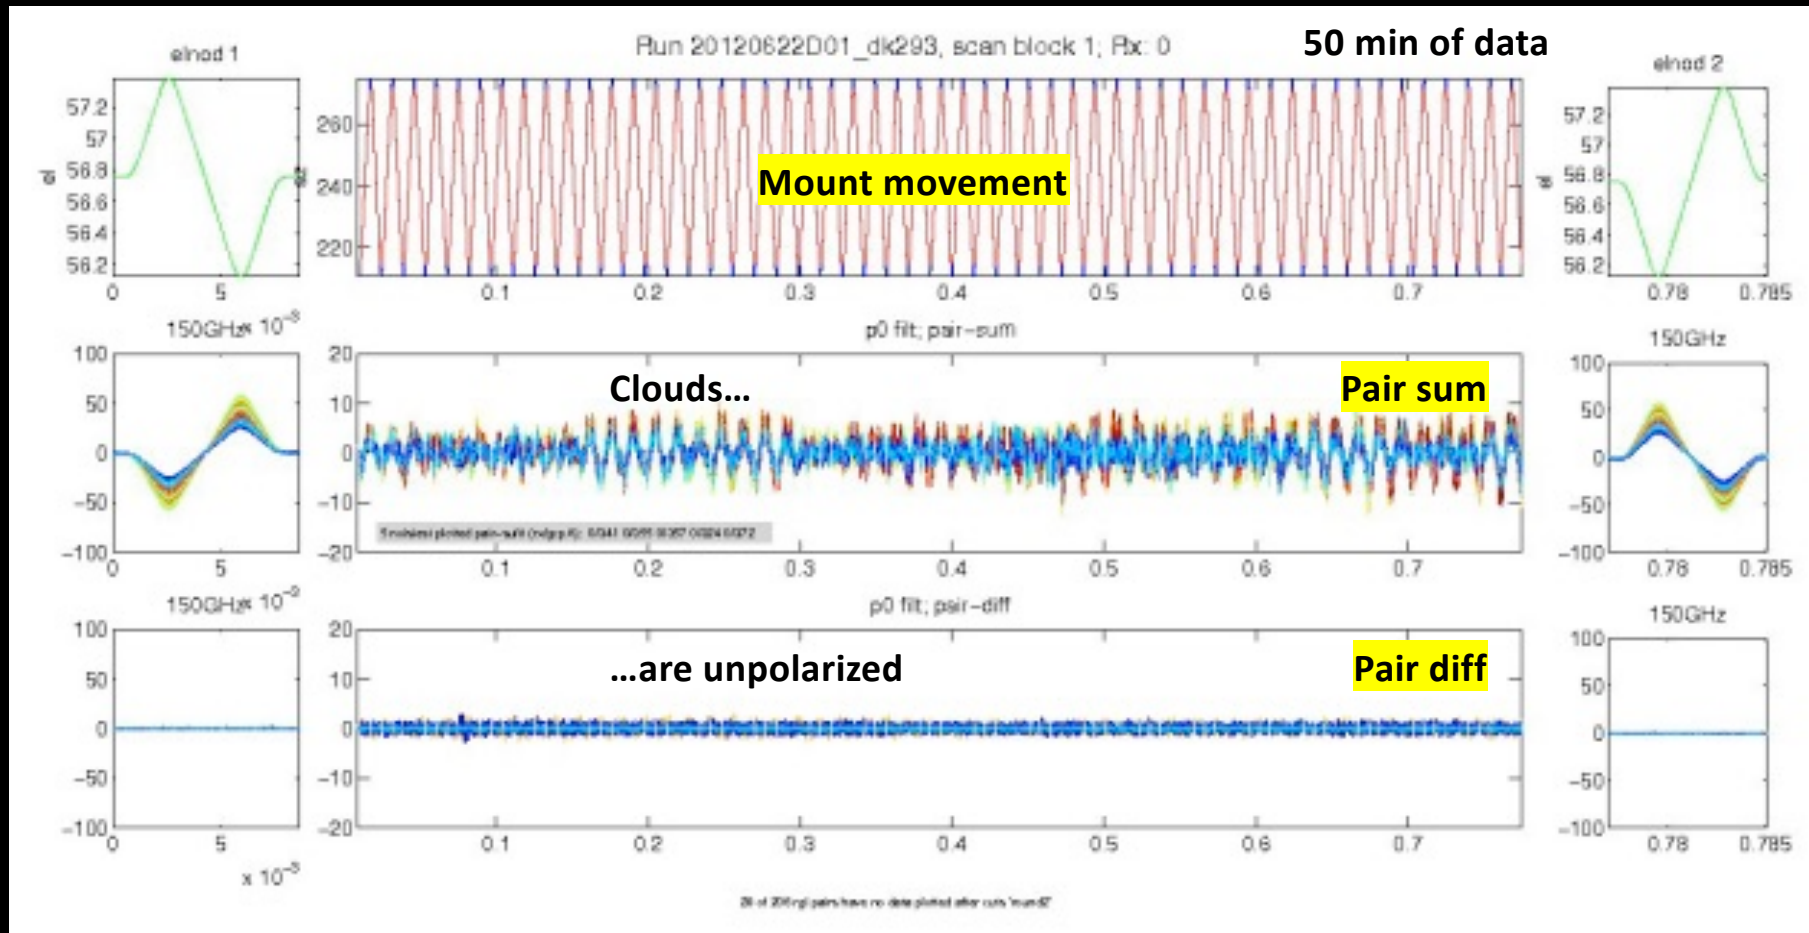

3) A single TES

Data analysis: example of data quality control

Data analysis: example of data quality control

Beam FWHM (arcmin)	76/57	24	15	10/8.5

3) A single TES

TKIDs physics: kinetic inductance detectors 101

- A) A photon or phonon breaks a Cooper pair
- B) The photon or phonon is absorbed in an inductor used in a resonant circuit changing the kinetic part of the inductance.
- C) By probing the resonant circuit with a “tone” close or on resonance, the transmitted power variation can be measured as well as
- D) The variation in phase.

Quasiparticles count in function of temperature:

$$n_{th}(T) = 2N_o \sqrt{2\pi k_B T \Delta} e^{-\Delta/k_B T}$$

$$\Delta = 1.76 k_B T_c$$

A small variation in quasiparticle population drastically changes the transmission function

TKIDs physics: kinetic inductance detectors 101

- Because each detector has a unique resonant frequency, we can couple multiple KIDs to a single RF line
- There is no need for SQUIDs or other cold electronic (other than a good LNA amplifier)
- Potentially, many wafers can be daisy chained.

S21 transfer function example using superconductive resonators

TKIDs physics: thermal kinetic inductance detectors

- The photon does not impact directly on the inductor
- Quasiparticle production is mediated by phonons
- The absorber can be a resistor (for calibration) or an antenna:
AC-TKIDs
- Decoupling design parameters (the inductor is not the antenna)
- The island (in red) is connected to the rest of the wafer via small supports or legs
- P_{opt} is the incoming optical power
- P_{read} is the readout power
- P_{leg} is the power dissipated by the island through the supports

TKIDs physics: thermal kinetic inductance detectors

A single TKID

Zoom on the Island

Heater

Inductor

TKIDs physics: thermal kinetic inductance detectors

$$S_{21} = 1 - \frac{Q_r}{Q_e} \frac{1}{1 + 4Q_r^2 x^2}$$

Effective coupling

$$Q_e = Q_c \cos(\phi_c) e^{j\phi_c}$$

Mattis Bardeen + background quasiparticles is the best fit

Readout strategies

Fixed multi-tone readout:

An RF signal is transmitted on resonance on each detector. The return signal phase and magnitude are monitored and, using the measured transfer function, converted into frequency and quality factor shifts. Available on our opensource software

Chirp readout:

A sinusoid with increasing frequency is transmitted on the full bandwidth. The energy accumulated by the chirp pulse in the resonators is released shortly after. The return signal spectrum contains the resonators ringdown. Available on our opensource software

Tone tracking:

Like the single tone readout but in this case the frequency of the generated tones follows the shift of the resonators. Requires a short loop latency between tx signal generation and rx analysis. Currently only available on custom FPGAs firmware due to GPU – DAC/ADC loop latency.

Software available at http://www.its.caltech.edu/~minutolo/gpu_sdr_doc.html

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

System level design: test arrays

Test arrays have a resistor instead of an antenna on the island

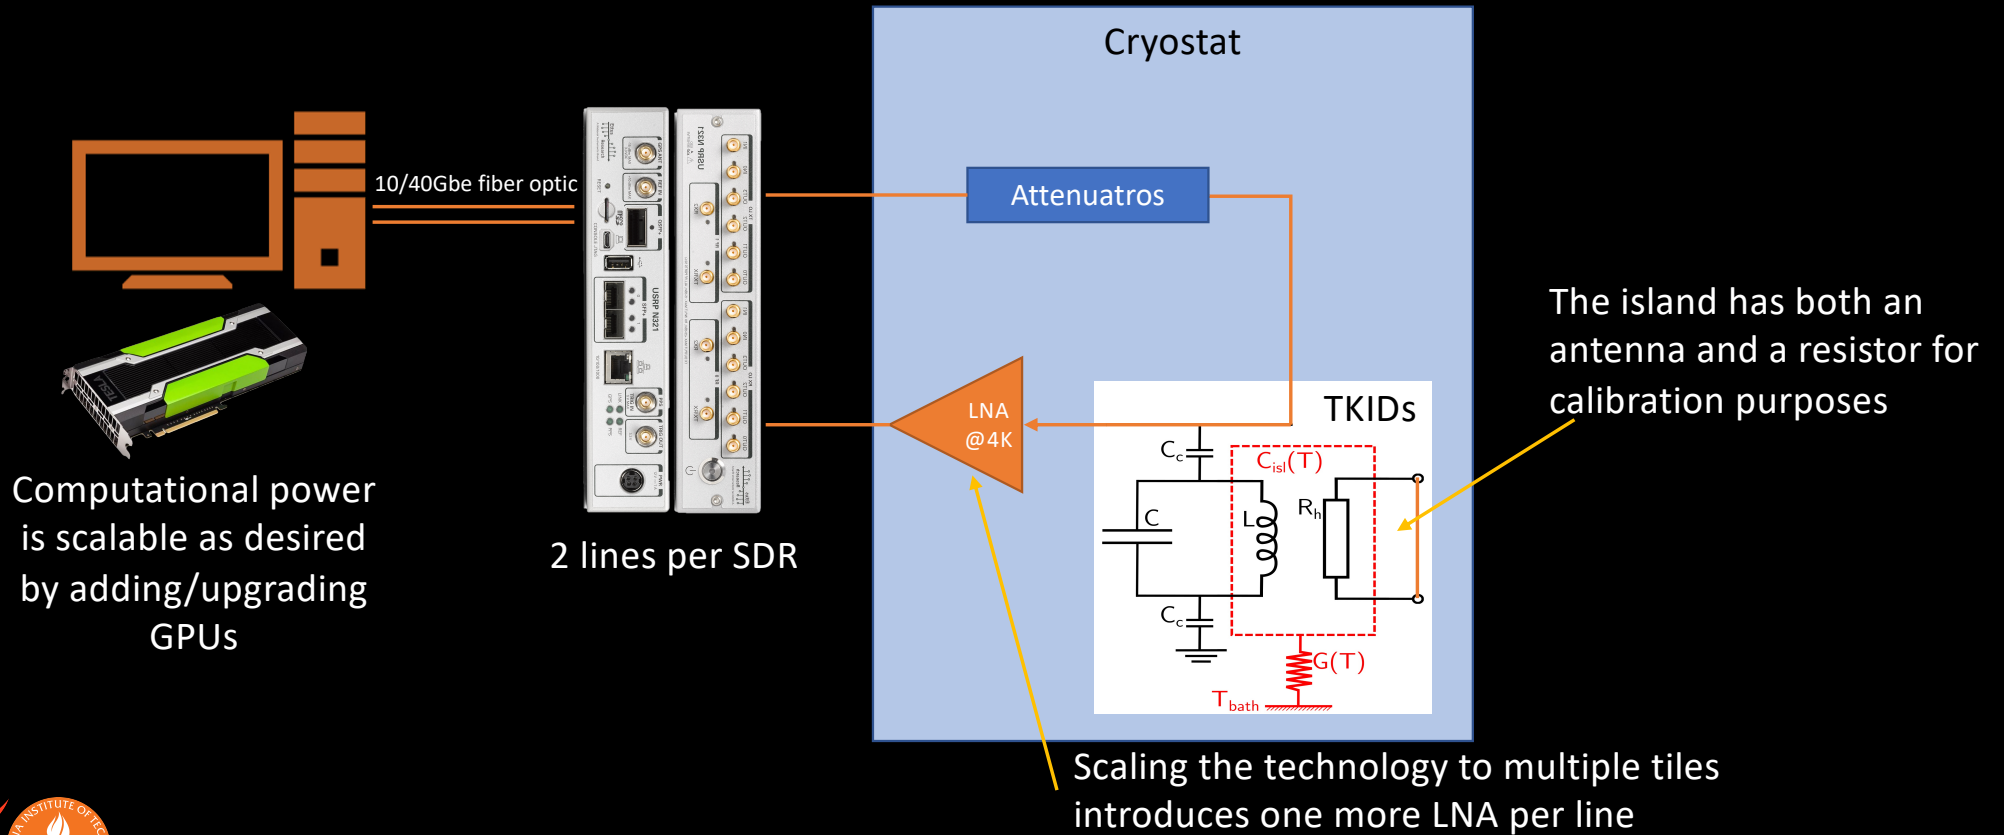

Nvidia GPUs for heavy data processing and stimulus generation

Software Defined Radio, Ettus USRP
200 MHz BW per line

System level design: AC-TKIDs

AC arrays have a 150 GHz antenna on the island: the optical band has been selected to benchmark the camera against existing TES measurements.

System level design: frequencies

GPU buffer generation
generate $X_S = \sum A_i e^{-i\omega_i t + \phi}$

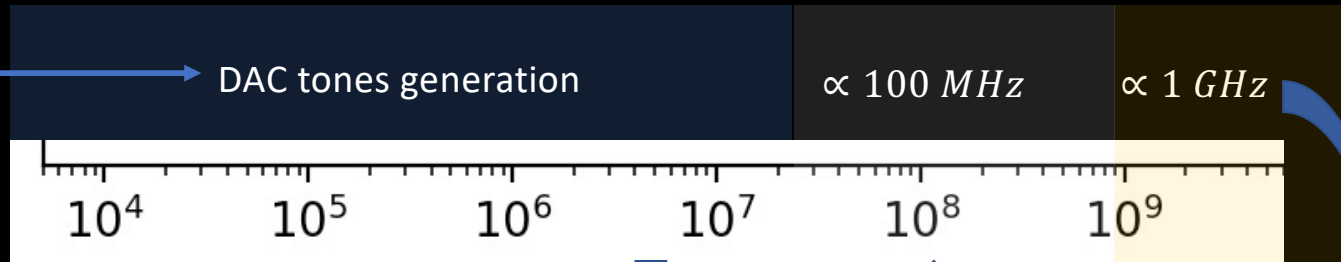

DC: $F(A_i, t)$ and
 $F(\phi_i, t)$ or $S_{21}(\omega_i)$
contain science

Internal TX mixer (tunable with ω_{LO}):
 $X_{RF} \approx e^{-i\omega_{LO} t} \cdot X_S$

Internal RX mixer (tunable, we use the same ω_{LO}):
 $F(X_{RF}) \cdot e^{-i\omega_{LO} t} \approx F(X_S)$

GPU demodulation, filtering and decimation:
each channel is $F(A_i) \approx F(X_S) \cdot e^{i\omega_i t}$

ADC readout

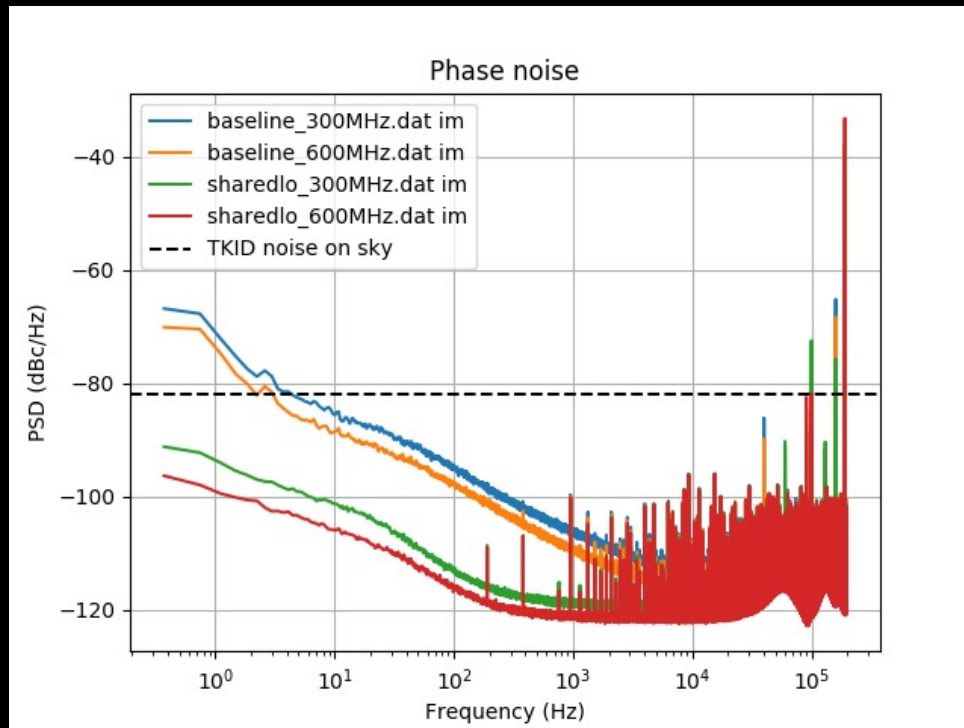

Loop through the cryostat
 $F()$

Sps or Hz

System level design: digression on electronics

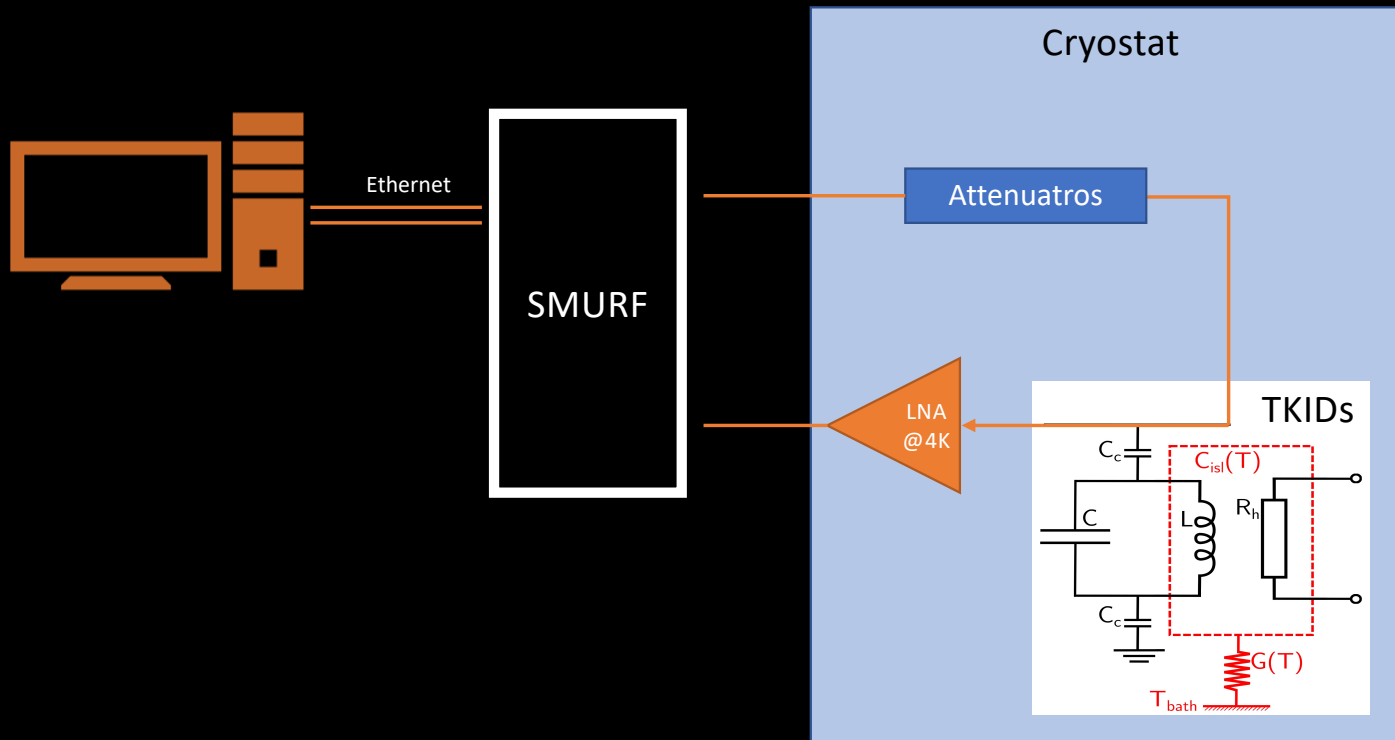

Using a single LO to upmix/downmix the signal improves performance

We could also evaluate using a low phase noise external LO to do this

Electronics: TKID – SMURF, tone tracking

SMURF uses tone tracking technology to read the detectors combining the best of both worlds: low noise and high responsivity.

Calibration and responsivity

Driving the resistors on the island with a known current we can calibrate our detectors

150GHz South Pole atmosphere provides
~5pW loading

Noise performance (dark)

$P_{\text{heater}}=4\text{pW}$ $T_{\text{isl}}=320\text{mK}$

$P_{\text{heater}}=10\text{pW}$ $T_{\text{isl}}=422\text{mK}$

At the South pole we expect $\sim 350\text{mK}$ and 6pW

Lorenzo Minutolo - BICEP Array and Thermal Kinetic Inductance Detectors

Detector stability

1/f Noise will be reduced by using the electronics in a configuration in which a single LO is present

Furthermore the polarization signal is obtained as a combination between two detectors with polarized antennas – common mode noise won't be critical

1.4 Hz is the frequency of our pulse tube

TKID Arrays

Dark device, 10 TKIDs

Dark device, 36 TKIDs, half with island not released from wafer. Allowed cosmic ray susceptibility testing

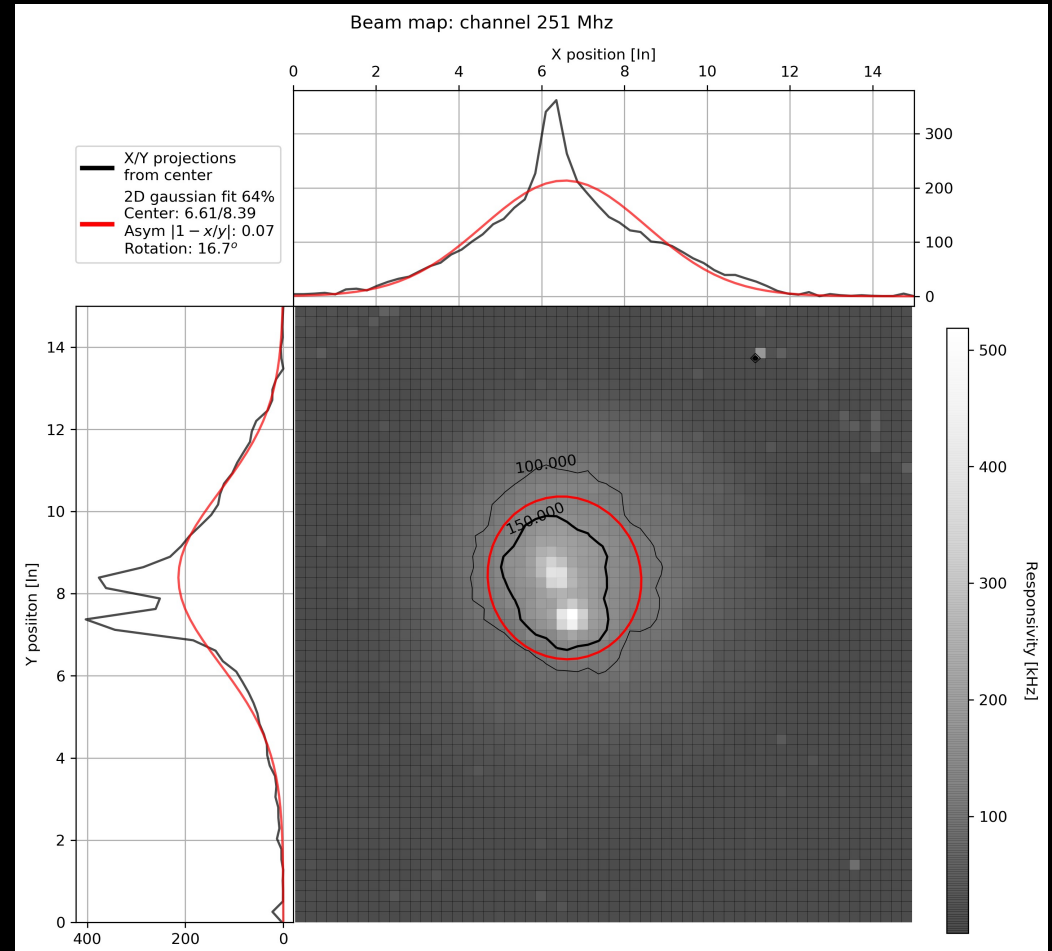

12 AC-TKIDs:
First light

First light: beam maps

First AC-TKIDs beam map:

- the beam profile look gaussian(ish)
- Next iteration has learned a lot from this run
- Detector non-linearity has been addressed using fast-chirp readout
- On the same tile *dark* detectors were present: the pickup of detectors without antenna is negligible (!)

FTS Spectroscopy

- Band determined by microstrip filter between antenna & bolometer
- Design: 27% around 145GHz
- Used Fast chirp readout to deal with nonlinearity also in this case
- Optical efficiency: 28%

Current development and plans

- Currently fabricating full arrays of antenna-coupled TKIDs
- Retrofitting Keck Array camera for a 150GHz Focal Plane
- To deploy to BICEP Array in 2021-22 austral winter
- Developing modular version for a BICEP Array camera
- Will deploy 220-270GHz camera 2022-23 austral winter
 - part microwave-mux TESes
 - Part TKIDs

Current development and plans: focal plane distribution board

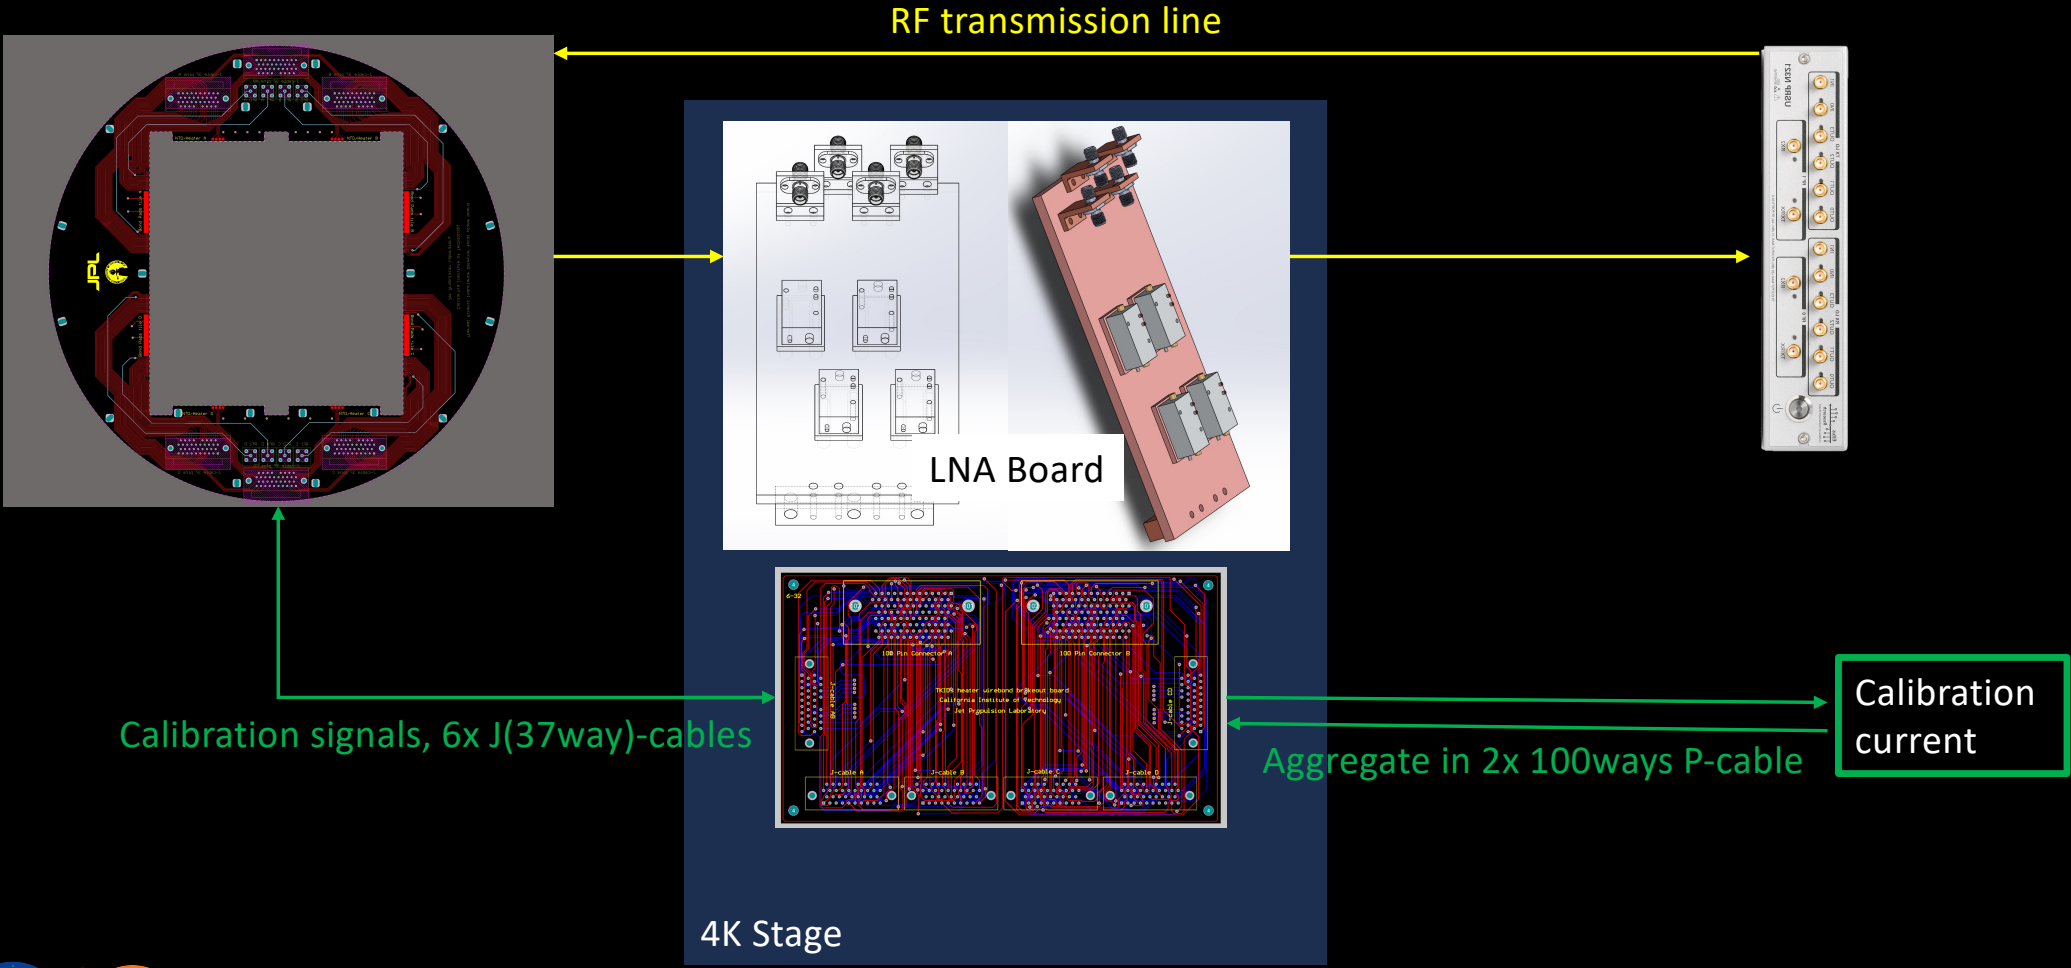

Lines breakout per tile: total

- 8 diff heater: 64
- 2 diff AL test structure: 16
- 4NTD+/Heater: 16
- 2 RF lines per tile: 8 SMA

Six layers board: heater signals separated from RF signals with 2x ground planes

Current development and plans: calibration signal distribution

Deployments plans
