## Chaotic hypothesis, Thermostats, SRB distributions

(http://ipparco.roma1.infn.it)

Thermodinamics  $\rightarrow$  equilibrium  $\rightarrow$  states  $\equiv$  dist. probab. on phase space Non Equilibrium: stationary state: distrib. probab. as well

Aim: look for "universal" relations translating structural properties like:

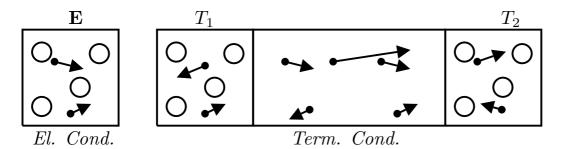

Hamiltonian 
$$H = K + U$$
, &  $K = \sum_{i=1}^{N} \frac{1}{2} m \dot{\mathbf{x}}_i^2$ ,  $U = \sum_{i < j} \Phi(\mathbf{x}_i - \mathbf{x}_j)$ 

+ ergodic hypothesis  $\Rightarrow$  Second Law (Boltzmann: trivial identity for 1 degree of freedom but not for  $10^{23}$ ).

## Example 1: Drude's Model (1899)

 $m\ddot{\mathbf{x}} = \mathbf{E} + \text{collision rule}$ 

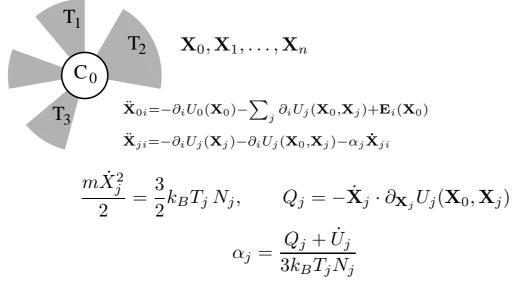

collisions= elastic + rescal. velocity to  $|\dot{\mathbf{x}}| = \sqrt{\frac{3}{m}k_BT}$ .

Problem:  $\langle \dot{\mathbf{x}} \rangle = cE$ ? (Ohm). Theorem if N=1 (ECLS).

**Example 2:** Heat conduction. Fourier law? Open problem. A conjecture ("YES", "NO").

General thermostat model

Efficient? when? Phase Volume contraction  $\Rightarrow$  divergence

$$\sigma = \varepsilon + \dot{V}, \qquad \varepsilon \stackrel{def}{=} \sum_{j \ge 1} \frac{Q_j}{k_B T_j}, \quad V \stackrel{def}{=} \sum_{j \ge 1} \frac{U_j}{k_B T_j}$$

Kinetic interpretation of entropy creation:

$$S - E \stackrel{def}{=} \frac{1}{\tau} \int_0^{\tau} \sigma(S_t(\dot{X}, X) dt - \frac{1}{\tau} \int_0^{\tau} \varepsilon(S_t(\dot{X}, X) dt = \frac{V(\tau) - V(0)}{\tau} \xrightarrow{\tau \to \infty} 0$$

E and S have intrinsically equal average  $\langle \varepsilon \rangle \equiv \langle \sigma \rangle \Rightarrow (\tau \to \infty)$  equal statistics for  $p = \frac{E}{\langle \varepsilon \rangle}$  and  $p' \stackrel{def}{=} \frac{S}{\langle \sigma \rangle}$ .

If chaotic (hyperbolic, regular, transitive) p' (hence p) satisfies "large deviations",  $\exists \zeta(p)$  analytic in  $(p_1, p_2)$ , convex, max at  $\langle p \rangle \equiv 1$ 

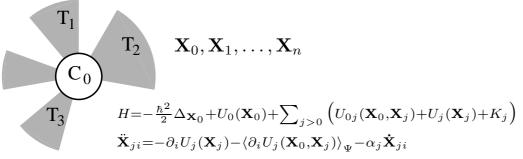

$$P_{\tau}(p \in [a, b]) \simeq e^{\tau \max_{[a, b]} \zeta(p)}, \quad \forall a, b \in (p_1, p_2)$$

if  $\zeta(p)$  quadratic at  $1 \Rightarrow$  Central limit theorem.

## Chaotic Hypothesis

The attractor for mechanical systems is hyperbolic, regular, transitive Analogous to the Ergodic hypotesis (which it implies)

Quantum Mechanics Finite thermostats

H operator on  $L_2(\mathcal{C}_0^{3N_0})$ , symm. or antisymm. waves  $\Psi$ ,  $Dynamical\ System\$ phase space is  $(\Psi, (\{\mathbf{X}_j\}, \{\dot{\mathbf{X}}_j\})_{j>0})$ :

$$-i\hbar\dot{\Psi}(\mathbf{X}_{0}) = (H\Psi)(\mathbf{X}_{0}),$$

$$\ddot{\mathbf{X}}_{j} = -\left(\partial_{j}U_{j}(\mathbf{X}_{j}) + \langle\partial_{j}U_{j}(\mathbf{X}_{0}, \mathbf{X}_{j})\rangle_{\Psi}\right) - \alpha_{j}\dot{\mathbf{X}}_{j} \quad j > 0$$

Constraint  $K_j$  constant  $\Rightarrow$ 

$$\alpha_j \stackrel{def}{=} \frac{\langle W_j \rangle_{\Psi} - \dot{U}_j}{2K_j}, \qquad W_j \stackrel{def}{=} -\dot{\mathbf{X}}_j \cdot \partial_j U_{0j}(\mathbf{X}_0, \mathbf{X}_j)$$
$$\sigma(\mathbf{X}, \dot{\mathbf{X}}) \equiv \varepsilon(\mathbf{X}, \dot{\mathbf{X}}) + \dot{V}(\mathbf{X}) = \sum_{j>0} \frac{Q_j}{k_B T_j} + \dot{V}$$

Consistency: single thermostat is SRB equivalent to Gibbs?

Chaotic hypothesis  $\Rightarrow$  unique statistics:  $\forall x$  up to 0 volume and  $\forall F$ 

$$\frac{1}{\tau} \sum_{j=0}^{\tau-1} F(S^j x) \xrightarrow{\tau \to \infty} \int F(y) \mu(dy)$$

 $\mu\stackrel{def}{=}$  SRB statistics: concentrated on volume 0 if  $\langle\sigma\rangle\stackrel{def}{=}\sigma_+>0$ 

Heuristic construction and meaning of SRB. Coarse graining.

 $\Rightarrow$  symbolic dynamics.  $\exists \mathcal{E} = (E_0, \dots, E_q)$  partition with "transition" or "compatibility" matrix

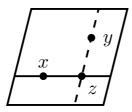

$$M_{\xi\xi'} = 1$$
, if  $SE_{\xi}^0 \cap E_{\xi'}^0 \neq \emptyset$ , = 0 otherwise

transitive  $(M_{\xi\xi'}^{\overline{\ell}} > 0)$ . Call  $E_{\xi}$  "coarse cells".

(a) If  $\boldsymbol{\xi} = (\dots, \xi_{-1}, \xi_0, \xi_1, \dots), M_{\xi_i \xi_{i+1}} \equiv 1 \iff \exists x \text{ and } S^i x \in E_{\xi_i}.$ 

(b) If  $\boldsymbol{\xi}, \boldsymbol{\xi}'$  corresp. x, x' and agree between  $-\tau$  e  $\tau \Rightarrow d(x, x') \leq Ce^{-\lambda \tau}$ 

- (c)  $E_{\xi}$  is foliated by  $W_s$  ( $W_i$ ), smooth & connected, with histories eventually equal in the future (past) and  $x, y \in W_s \Rightarrow d(S^n x, S^n y) \leq C e^{-\tau \lambda}$ .
- (d) If  $x, y \in E_{\xi} \Rightarrow z = W_i(x) \cap W_s(y) \Rightarrow d(S^k y, S^k z) \xrightarrow[k \to \infty]{} 0$  exponent.

 $W_i$  is asymptotically attracting.

Let  $\tau$  so large that *all* interesting observ. F are constant in the cells  $(\widetilde{\boldsymbol{\xi}} \stackrel{def}{=} (\xi_{-\tau}, \dots, \xi_{\tau}))$ 

$$E(\widetilde{\boldsymbol{\xi}}) \stackrel{def}{=} S^{\tau} E_{\xi_{-\tau}} \cap S^{\tau-1} E_{\xi_{-\tau+1}} \cap \ldots \cap S^{-\tau} E_{\xi_{\tau}} = \text{``coarse cells''}$$

Problem: time evolution cannot be a permutation (cells too large)

Immagine phase space discretized (Boltzmann) in *microcells*. As in simulations: a point  $\rightarrow$  64 bits per each of the  $\mathcal{N}$  coordinates:  $2^{64}\mathcal{N}$ .

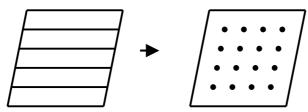

We wish  $\langle F \rangle$ .

The set  $\mathcal{A}$  of recurrent points is the *attractor*. Transitivity (generalization of "ergodic hypothesis")  $\Rightarrow$  1-cycle permutation.

Then average are computed with a uniform distribution!

$$\langle F \rangle = \frac{\sum_{\widetilde{\boldsymbol{\xi}}} \mathcal{N}(\widetilde{\boldsymbol{\xi}}) F(\widetilde{\boldsymbol{\xi}})}{\sum_{\widetilde{\boldsymbol{\xi}}} \mathcal{N}(\widetilde{\boldsymbol{\xi}})}$$

In the discrete representation  $\mathcal{A}$  appears, in each coarse cell, as a family of points regularly arranged on a finite number of unstable manifolds

The number  $\mathcal{N}(\widetilde{\boldsymbol{\xi}})$  is subject to a strong compatibility constraint.

If  $x \in E(\widetilde{\boldsymbol{\xi}})$  prefixed, let  $\Lambda_i(\widetilde{\boldsymbol{\xi}})$  the coefficient of expansion of the surface  $W_i(x)$  for the map  $S^{2\tau}$  (as map of  $S^{-\tau}x$  into  $S^{\tau}x$ ).

Compatibility 
$$\Rightarrow \mathcal{N}(\widetilde{\boldsymbol{\xi}}) = \cot \Lambda_i(\widetilde{\boldsymbol{\xi}})^{-1}$$

hence if  $\lambda_i(\widetilde{\boldsymbol{\xi}}) \stackrel{def}{=} \log \Lambda_i(\widetilde{\boldsymbol{\xi}})$ 

$$\langle F \rangle = \frac{\sum_{\widetilde{\boldsymbol{\xi}}} e^{-\lambda_i(\widetilde{\boldsymbol{\xi}})} F(\widetilde{\boldsymbol{\xi}})}{\sum_{\widetilde{\boldsymbol{\xi}}} e^{-\lambda_i(\widetilde{\boldsymbol{\xi}})}}$$

espressing the SRB distribution.

Applications? Fluctuation theorem of CG (very different from Evans-Searles), Onsager reciprocity, Green-Kubo.

If evolution is reversible (as in above models)  $\exists I$  such that  $I^2 = 1$ ,  $IS = S^{-1}I$ . Then  $\lambda_i(I\tilde{\xi}) = -\lambda_s(\tilde{\xi})$ 

11

Hence if  $p = \frac{1}{\tau} \sum_{j=0}^{\tau-1} \frac{\sigma(S^j x)}{\sigma_+}, \ \sigma_+ = \langle \sigma \rangle > 0$ 

$$\frac{P_{\tau}(p)}{P_{\tau}(-p)} = \frac{\sum_{\widetilde{\boldsymbol{\xi}}, p \text{ fixed}} e^{-\lambda_{i}(\widetilde{\boldsymbol{\xi}})}}{\sum_{\widetilde{\boldsymbol{\xi}}, -p \text{ fixed}} e^{-\lambda_{i}(\widetilde{\boldsymbol{\xi}})}} = \frac{\sum_{\widetilde{\boldsymbol{\xi}}, p \text{ fixed}} e^{-\lambda_{i}(\widetilde{\boldsymbol{\xi}})}}{\sum_{\widetilde{\boldsymbol{\xi}}, p \text{ fixed}} e^{-\lambda_{i}(I\widetilde{\boldsymbol{\xi}})}} = \frac{\sum_{\widetilde{\boldsymbol{\xi}}, p \text{ fixed}} e^{-\lambda_{i}(\widetilde{\boldsymbol{\xi}})}}{\sum_{\widetilde{\boldsymbol{\xi}}, p \text{ fixed}} e^{-\lambda_{i}(\widetilde{\boldsymbol{\xi}})}}$$

$$= e^{\tau p \sigma_{+}} \text{ because } -\lambda_{i}(\widetilde{\boldsymbol{\xi}}) - \lambda_{s}(\widetilde{\boldsymbol{\xi}}) = p\sigma_{+}\tau.$$

In terms of large deviations (Fluct. Theorem):  $\exists p^*$ 

$$\zeta(-p) = \zeta(p) - p\sigma_+, \quad \forall p \in (-p^*, p^*)$$

no parameters, model independent (provided reversible).

Verifiable in simulations and, in principle, in experiments, because of the interpretation of  $\sigma$  as entropy creation rate.
